Volga, W. Va.—J. T. Herbert and W. M. Miller, Cleveland, Ohio, and associates, have acquired approximately 300 acres of coal properties in Upshur County, W. Va., and are planning for immediate development.

Indian Head, Md.—The United States Government, Navy Department, has had plans prepared for the construction of a new coal storage basin at the local Government station, to cost approximately $125,000.

Buffalo, N. Y.—The General Anthracite Co. has been incorporated with a capital of $10,000 to engage in a general coal business. J. L. Ley, M. E. Sullivan and J. H. Watson, Buffalo, are the incorporators.

Middlesboro, Ky.—The Benite Coal Co. has been incorporated with a capital of $25,000 to operate coal properties in the Middlesboro section. S. E. and Samuel Bennett and W. M. Young are the incorporators.

Charleston, W. Va.—The Charleston Coöperative Coal Co. has been incorporated with a capital of $96,000 to operate coal mines in Kanawha County. Eugene J. and F. Fried and D. W. Dunbar are the incorporators.

Fontanet, Ind.—The Fontanet Coal Co. has been organized with capital of $30,000 to transact a general mining business. The directors are George H. Funk, S. J. Gregory, Fred B. Funk, Samuel Jaffee and John H. Gallagher.

Dayton, Ohio—Kentucky Hills Mining Co. has been incorporated with a capital of $25,000 to mine and sell coal. The incorporators are John A. Murphy, J. Francis Murphy, D. W. Allaman, R. B. Retter and D. A. Eichelberger.

Washington, D. C.—Effective Nov. 11, greater leniency is to be permitted in the use of electricity for signs and other of the less essential uses. Much of the jurisdiction in the matter has been vested in the state fuel administrators.

Pittsburgh, Penn.—The Pittsburgh-Midland Coal Co. has been incorporated under Delaware laws with a capital of $50,000 to engage in general coal-mining operations. L. A. Irwin, W. G. Singer and M. L. Rogers are the incorporators.

Covington, Ky.—The Murphy-Daugherty Coal Co. has been incorporated with a capital of $100,000 to develop coal properties in the Covington district. John T. Murphy, E. H. Daugherty and Martin Brown are the incorporators.

Scranton, Penn.—The Price-Pancoast Coal Co., Board of Trade Building, has completed arrangements for the erection of a new one-story electric plant, about 80 x 100 ft. at its properties at Throop, Penn. The structure will cost about $75,000.

Middlesboro, Ky.—The Benito Coal Co., which recently filed notice of incorporation with a capital of $25,000, is planning for the immediate development of about 631 acres of coal properties in the Evarts section. Samuel Bennett is president.

Louisville, Ky.—R. L. Watson, manager of the Byrne & Speed Co., Louisville, reports that he has on hand easily a month's supply of domestic coal in the company's local yards, and figures that most of the other retailers are in about the same boat.

Pittsburgh, Penn.—The Pennsylvania Lines West of Pittsburgh has awarded a contract to the Roberts & Shaefer Co., McCormick Building, Chicago, Ill., for the construction of a new coaling station at Mingo Junction, Ohio, of 700 tons capacity.

Philadelphia, Penn.—The Midvale Steel and Ordnance Corporation, Widener Building, has awarded a contract to the R. H. Beaumont Co., Drexel Building, for the installation of new coal- and ash-handling equipment at its Nicetown works to cost about $35,000.

Philadelphia, Penn.—Mortenthaler Brothers has awarded a contract to William F. Krelle & Co., Twenty-sixth and Oxford Sts., for the erection of a new concrete and steel trestle at its coal yards at Wolf and Swanson Sts. The structure will cost about $7000.

Morgantown, W. Va.—The Hice Coal Co. has been incorporated with a capital of $10,000 to develop coal properties in the vicinity of Morgantown. James R. Moreland, Morgantown; H. C. Kifer, Manor, Penn.; G. C. M. Hice and S. B. McNeill, Brooklyn, N. Y., are the incorporators.

Lynch, Ky.—The United States Coal and Coke Co. at a cost of $100,000 will build reinforced concrete bins, one story high, 45 x 60 x 132 ft. and 45 x 45 x 20, to take care of production awaiting shipment. The construction work will be handled by N. N. Eavenson, of Gary, W. Va.

Charleston, W. Va.—The Capital Issues Committee has granted approval of the proposed issue of securities for $150,000 by the Eagle Byproducts Co., the proceeds to be used for extensive additions to its byproduct coal plant to increase the present capacity to approximately 1500 tons daily.

St. Mary's Falls Canal, Mich.—Statistics compiled under the direction of Col. F. W. Alstaetter, Corps of Engineers, U. S. Army, show that during the month of October 3,087,728 net tons of soft coal and 403,510 net tons of hard coal passed through the Sault Ste. Marie, Michigan and Ontario canals.

Hickman, Ky.—Rains during the past few days and higher water in the Ohio are expected to result in a larger volume of western Kentucky coal moving South via the Ohio and Mississippi. The river has been so low all summer that even small boats had much trouble, and small tows were forced to double trip at numerous points.

Lynch Mines, Ky.—The United States Coal and Coke Co., Carnegie Building, Pittsburgh, Penn., has completed arrangements for the construction of a new reinforced-concrete coal bin, one-story, about 45 x 60 x 132 ft., at its local properties. The structure is estimated to cost $100,000. N. N. Eavenson, Gary, W. Va., is the contractor.

Columbus, Ohio—Announcement is made by A. H. Smith, regional director of railroads, that F. B. Sheldon, heretofore general manager of the Toledo & Ohio Central, the Kanawha & Michigan and the Zanesville & Western railroads, has been made federal manager of the above-mentioned lines. His headquarters will continue at Columbus.

Fairmont, W. Va.—The Domestic Coke Corporation has awarded a contract to the H. Koppers Co., Pittsburgh, Penn., for the installation of a battery of 60 coke ovens at its properties. The new plant will be located on a 45-acre site and it is proposed to produce about 450 gal. of toluol and 13½ tons of ammonia sulphate daily for Government use.

Charleston, W. Va.—The Kanawha Collieries Co., recently incorporated with a capital of $100,000, has taken bids for the installation of mining machinery, etc., for the development of approximately 1200 acres of coal properties in the vicinity of Swiss, W. Va. It is proposed to have a capacity of about 1000 tons daily. William G. Conley is president.

Washington, D. C.—To combat extortionate prices being charged for storing of coal in the District of Columbia, the fuel director for the District has issued an order, which reads: "All retail coal dealers are hereby directed to arrange for and store all coal delivered by them to residences, whenever requested by the purchaser, at a cost not to exceed 75c. a ton."

Uniontown, Penn.—Work has been commenced on developing a 90-acre tract of coal along the Monongahela River by the Gallatin Coal Co., consisting of Frank B. Hess, A. Q. Davis, of Uniontown, and James Baird, of Brownsville. Operations are expected to be commenced Jan. 1. Shipments will be made exclusively by river. Both Mr. Hess and Mr. Davis are interested in several other coal companies.

Henderson, Ky.—The Audubon Mining Co., operating at this point, and formerly owned by Henderson capital, has passed into the hands of a Nashville syndicate of capitalists, who for the present will operate the company under the old title. The same interests recently purchased the Uniontown Mining Co., at Uniontown, Ky. W. L. Hughes, manager of the Audubon company, will continue in charge of operations.

Charleston, W. Va.—Webster County coal lands, almost a virgin field, will undergo development if present plans of Philadelphia capitalists are carried out, the Beaver Run Coal Co. having been organized with a capital of half a million to operate mines near Holly, W. Va. The incorporators are H. Chester Johnson, Horace S. Glazier, Charles F. Pike, J. R. Ives, all of Philadelphia, and John M. L. Black, of Villa Nova, Penn.

Uniontown, Penn.—Sections of double tracks between Uniontown and Morgantown, W. Va., are being placed by the Baltimore & Ohio Railroad Company to care for the increased coal and coke traffic from the West Virginia field. The improvements were commenced last week and will continue for a period of a year or more. For some time past the Baltimore & Ohio has been strengthening its lines at different points to handle the heavy traffic.

Burgettstown, Penn.—The coal department of the American Zinc and Smelting Co. will install at its Langeloth mine, Slovan, Washington County, Pennsylvania, a complete new equipment for coal preparation. The structure will be of steel and will include shaking screens, picking tables and loading booms. C. L. Miller & Co., of Scottdale, Penn., will furnish the equipment. Baton & Elliott, of Pittsburgh, Penn., are the engineers. The work of installation will be under the direction of R. E. Bucknam, superintendent of the mine.

Lexington, Ky.—R. A. Hord, secretary of the Hazard Coal Operators Exchange and Deputy U. S. Fuel Administrator for eastern Kentucky, reports that coal mining operations as late as Nov. 7, were still handicapped by the influenza epidemic to the extent of at least 50 per cent, if not more. While conditions are clearing up somewhat in some sections others are showing an increase in the number of cases, resulting in miners becoming panicky and crippling production. With more nurses and doctors pouring into the fields he expects conditions to mend soon.

Chattanooga, Tenn.—The Suck Creek Co. has been organized to engage in the development of coal mines in the Signal Mountain territory. It is understood that a large tract, comprising several thousand acres, has been acquired under lease, and that the company is planning for immediate development. It is proposed to handle the product by incline to the Tennessee River, near the mouth of Suck Creek, and thence to Chattanooga, a distance of about three miles, in barges. Richard Hardy is president; Z. C. Patton, Jr., vice president; and George Killian, secretary and treasurer.

Uniontown, Penn.—Ninety acres of the Pittsburgh vein of coal fronting the Monongahela River have been acquired by Frank B. Hess and A. Q. Adams, of Uniontown, and James Baird, of Brownsville, who have organized the Gallatin Coal Co. to develop the tract. Work is now being rushed preliminary to opening a mine, and the company expects to commence operations by Jan. 1. Shipments will be made exclusively by river. Messrs. Davis and Hess own the Provins coke plant at Waltersburg, this district, and are also interested in the Davis Fuel Co. of Morgantown, a brokerage concern.

Toledo, Ohio — Indications point to a rather early closing of the lake season, because of the fact that the tonnage required for the Northwest has been moved and also because of a shortage of labor on the docks of the upper lake ports. So it is unofficially stated that shipments of coal from the mines for lake traffic will stop Nov. 15, and that all vessels will leave on their last trip Nov. 23. During the week ending Nov. 2 the Hocking Valley docks loaded 140,564 tons as compared with 259,572 tons during the previous week. The total loaded during the season amounts to 4,634,569 tons. During the same week the Toledo & Ohio Central docks loaded 65,000 tons as compared with 78,000 tons the previous week, making 2,017,075 tons for the season.

Washington, D. C.—Bituminous coal-producing companies over the country were called upon by J. H. Wheelwright, president of the National Coal Association, to contribute at least one-quarter of 1 per cent. of their capital stocks to the $170,500,000 United War Work Campaign Fund, the nation-wide drive for which begins Monday, Nov. 11. In addition, Mr. Wheelwright expressed the hope that all employees of bituminous coal-producing companies, estimated at more than 600,000, would give a day's pay during November to the fund. Representatives of the miners in the bituminous fields were urged to cooperate with the local war work campaign committees in "soliciting each employee to sign a pledge, the amounts thus pledged to be collected and turned over to either the local, state, or national campaign committee."

Charleston, W. Va.—Because of the restrictions placed upon them as to the territory into which they can dispose of their coal, producers in Zone "L," which includes the plants shipping over the Kanawha & Michigan, Kanawha & West Virginia Ry. and the Coal & Coke Ry. west of Dundon, have asked for a modification of the present zone limits prescribed by the Zone Permit Bureau on Oct. 10. With the present restrictions in force a limited portion of Ohio and the lower peninsula of Michigan for lump coal is the only territory into which the producers alluded to can ship. Under the new ruling, existing contracts for malleable lump coal and steam mine-run are in effect abrogated. Before the new ruling went into effect the producers in Zone "L" were permitted to ship to Ohio, Indiana and southern Michigan. Should the Zone "L" producers be able to secure a modification of the October 10 ruling this territory would be restored to them.

Washington, D. C.—A new order by the Federal Fuel Administration, effective Nov. 11, states that "the use of light generated or produced by the use or consumption of coal, oil, gas or other fuel, for illuminating or displaying advertisements, announcements or signs on the exterior of any building, or on any billboard, or other structure for the display of advertisements, announcements or signs, and the use of such light for the external ornamentation of any building or structure, or for illuminating or displaying any window in any shop or store, when such shop or store is not open for business, shall be entirely discontinued on Monday, Tuesday, Wednesday and Thursday of each week in New England, and in the States of New York, Pennsylvania, New Jersey, Delaware, Maryland, and in the District of Columbia, and shall be entirely discontinued on Monday and Tuesday of each week in the States of Michigan and Ohio, and in any state not hereinbefore mentioned, when the Federal Fuel Administrator for such state shall so order, provided however, that nothing in this regulation shall be construed to prohibit the maintenance in any shop or store window of any lights required by a state law or a municipal ordinance, or for the purpose of safety."

MARKET DEPARTMENT

Weekly Review

Cessation of Hostilities Brings Its Problems to Bituminous Operators—Consumers Well Stocked with Coal—Buyers Conspicuous by Their Apathy—Danger Ahead for Consumers Who Do Not Replenish Their Stocks—Anthracite Situation

IN RESPONSE to the Fuel Administration's campaign for a maximum coal output there was produced during the first seven months of the present coal year (April to October inclusive) 368,858,000 net tons of bituminous coal. This tonnage represents an increase of 42,437,000 net tons over the output of the similar period in 1917.

With the country driving ahead at full blast on a war program, the increased rate of production was far from being sufficient to meet the demands of industry. Industries that were considered unessential to the war program were denied the use of coal, the extent of the stocks that would be accumulated by essential industries was specified by the Fuel Administration, and a zoning system was perfected which had for its object the elimination of the cross-hauling of coal from one mining section to another. These changes, and many others even more radical, were instituted for the sole purpose of enabling the country to concentrate its energies on one thing—the carrying on of a war that would bring about a speedy peace.

Now, 19 months after our entry into the conflict the war has come to an end. Though indications were many that the German war machine was disintegrating, still the end came with a suddenness which for this country was startling. Just as in the beginning our declaration against autocracy found us unprepared for war, so the signing of the armistice on Nov. 10 finds us unprepared for peace. This is evidenced by the fact that we have not, at this writing, passed one bit of legislation looking toward a well-defined reconstruction program.

The cessation of hostilities has, if anything, brought forcibly to the attention of the soft-coal operators the realization that they are confronted by a situation that threatens to become serious. Thanks to the methods pursued by the Fuel Administration, consumers of bituminous coal in almost every section of the country have large reserve stocks on hand. To put it plainly, there is an oversupply of soft coal in the hands of consumers, and many mines that but a short time since were hard put to it to meet their production quota now find that they are unable to dispose of their output. The steel mills and the blast furnaces, for instance, are loaded down with coal, and until they can utilize their large stocks in the manufacture of peacetime products they will not come into the market for additional supplies.

The foregoing is true of almost every other industry. Buyers who a month or so ago were eager, even clamorous, to obtain a meager tonnage, are running along from hand to mouth in the hope of a break in the market that will enable them to buy fancy grades below the present Government prices. However, there is more than a possibility that these schemes will miscarry. As industries one after the other return to the manufacture of their pre-war products, and plants that were not permitted to function, or that were curtailed, resume full-time operations the shortage which now exists on paper in the Fuel Administration records may become a sad reality. Weather conditions, too, up to the present have aided those who are laying low on their purchases, and the mine workers have given of their best because they did not desire to interfere with the country's war program. Who can tell how long these favorable conditions will continue?

A quite different aspect is presented by the anthracite market. In fact, reverse what has been said of soft coal and the hard coal situation stands revealed. A shortage of labor during the entire war period, and an influenza epidemic to cap the climax, as it were, has brought the output of anthracite from April 1 to date behind the total production for the corresponding period of 1917. Estimates place the 1918 production from April 1 to November 2 at 60,588,000 net tons and 1917 production at 60,839,000 net tons. However, the discontinuance of munitions manufacture and the shutting down of other strictly war-work industries will doubtless lead to the return of many mine workers (particularly since the new wage increase in the hard coal industry has gone into effect) and before long it is possible that the output of anthracite may show the eagerly awaited upward trend.

WEEKLY COAL PRODUCTION

The production of bituminous coal during the week of Nov. 2, as in the preceding four weeks, continued on the downward grade, estimates placing the output (including lignite and coal made into coke) at 10,965,0d0 net tons, a decrease compared with the preceding week of 3 per cent. and but 0.6 per cent. over the corresponding week of 1917. The average production per working day during the current week is estimated at 1,828,000 net tons as against 1,885,000 net tons during the week of Oct. 26 and 1,816,000 net tons during the week of Nov. 2 of last year.

This is the nearest approach to the level of 1917 since last February and indicates that, unless production soon increases, the probability of a shortage, largely overcome by the record-breaking output of the past few months, will again be before the country. The epidemic of influenza still continues in some of the fields and to this, together with the unexpected warm weather generally, is attributed a temporary lull in the production and transportation of coal and in the previous strenuous industrial demand.

The production of bituminous coal from April 1 to date is 368,858,000 net tons as against 326,421,000 net tons in 1917, an increase of 42,437,000 net tons or 13 per cent.

Anthracite production continued to fall during the week of Nov. 2, estimates placing the output at 1,500,000 net tons as compared with 1,714,000 net tons during the week preceding, a decrease of 214,000 net tons or 12.5 per cent. The current week's production fell even further behind the corresponding week of 1917, the decrease amounting to 547,000 net tons, or 27 per cent. The daily average during the week ended Nov. 2 is estimated at 250,000 net tons as compared with 331,000 net tons, the daily average for the coal year to date and as against 332,000 net tons, the daily average for the coal year 1917. For the first time the production from Apr. 1 to date falls behind the total production for the corresponding period of 1917, estimates placing the 1918 production from Apr. 1 to Nov. 2 at 60,588,000 net tons and 1917 production at 60,839,000 net tons.

Carriers' reports for the week of Nov. 2 show a decrease in shipments from all districts compared with the preceding week with the exception of Cumberland-Piedmont and Somerset, Fairmont, Tennessee and Kentucky, the Illinois, Indiana and western Kentucky district and the districts west of the Mississippi River. In these fields the increase is slight while decreases during the week occurred in central and western Pennsylvania, Ohio, the district including northeast Kentucky and the high and low volatile fields of southwest Virginia and Alabama. All fields, however, report an increase in shipments for the coal year to date over the corresponding period of 1917.

Bituminous coal dumped at lake ports during the week ended Nov. 2 is estimated at 826,224 net tons, a decrease compared with the week preceding of 20 per cent. This tonnage, while low, did not fall behind the requirements outlined by the United States Fuel Administration for this period of the year, and it is now certain that the original lake program will be met before the end of November.

Shipments of bituminous coal to New England during the week ended Nov. 2 are estimated at 473,932 net tons, an increase over the shipments of the week preceding of 7 per cent. This increase is attributed mainly to extremely heavy movement of tidewater shipments during the current week, exceeding the performance of the week preceding by approximately 21 per cent., while rail receipts declined 21 per cent. Shipments also increased from all harbors and with the exception of Hampton Roads exceeded the weekly average for the coal year to date. Rail receipts as well as the total coal to New England fell behind the weekly average.

Tidewater shipments of bituminous coal from all harbors during the week ended Nov. 2, estimated at 819,761 net tons, are

approximately the same as the shipments during the week of Oct. 26 and fell behind the weekly average for the coal year to date by approximately 8 per cent. Shipments during the week of Nov. 2 increased slightly from Baltimore, while shipments from New York, Philadelphia and Hampton Roads fell slightly behind. Compared with the weekly average, Baltimore was the only port reporting an excess.

The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production of beehive coke during the week of Nov. 2 at 339,139 net tons and the operation of their plants at 73.1 per cent. as against 73.9 per cent. during the week preceding. A slight improvement was noted during the week in labor conditions.

The production of beehive coke in the United States for the week ended Nov. 2 is estimated at 558,000 net tons, a decrease of 6 per cent. compared with the week preceding and 4 per cent. compared with the corresponding week of 1917. The daily average is estimated at 93,000 net tons as against 99,000 net tons during the week of Oct. 26 and 97,000 net tons during the week of Nov. 2 of last year. For the calendar year to date beehive coke production is estimated at 26,104,758 net tons as against 28,186,100 net tons during the same period of 1917 or a decrease of 2,081,342 net tons or 7.4 per cent.

The production of byproduct coke in the United States during the week ended Nov. 2 is estimated at 577,006 net tons, as compared with 434,881 net tons during the corresponding week of 1917, or an increase of approximately 33 per cent. The production during the current week was brought about by the operation of the byproduct plants at 89.6 per cent. of their full time. Out of a total loss of full time of 10.4 per cent. 1.1 per cent. is attributed to lack of coal, 1.2, per cent. to labor shortage, 6.3 per cent. to repairs to plants and 1.8 per cent. to other causes.

Operating conditions failed to equal those of the preceding week in Illinois, Maryland, Minnesota and Ohio. In Illinois, the output of the plants was limited by both shortage of coal and repairs to plants, in Ohio by repairs to plants and other causes, in Maryland by shortage of labor, and in Minnesota by other causes. No material improvement was reported by the operators in any of the states.

Recalculation of even capacity causes an increase in capacity to be reported for certain states.

For the calendar year to date, the production of byproduct coke is estimated at 21,365,278 net tons, as compared with 18,830,410 net tons, or an increase of 13.4 per cent. The total production of beehive and byproduct coke, for the calendar year to date, estimated at 47,500,000 net tons, is but slightly in excess of the total production during the corresponding period of 1917. Of this 1918 total, approximately 45 per cent. is byproduct coke and 55 per cent. beehive, while during 1917, 40 per cent. of the total production was byproduct and 60 per cent. beehive.

Atlantic Seaboard

BOSTON

Heavy dull market. Steam plants stuffed with coal. Enough to last until April, in most cases. Cancellations general. Many consumers have difficulty with hot coal. Buyers feel that prices are sure to be lower in the spring. Hampton Roads dispatch fair. Something of a problem to place coal arriving at this end. "Storrow coal" at Baltimore shut off. Same action likely to be taken at New York piers. All-rail movement still further reduced. Few box cars now coming through. Rumored that New England Fuel Administrator may soon relinquish active handling of bituminous. Recent raising of limits for greenhouses, etc., has effect only locally and to very small degree. Railroads well stocked. New England holds no encouraging sign for operators who hope for full mining this winter. Anthracite receipts about on October level. Rail receipts slightly off, but water deliveries somewhat improved. Surplus of broken and pea being worked off very slowly. Latest advance accepted with little comment.

Bituminous—The trend of the war is having its effect on the market. Only a few weeks ago a large number of buyers were ready to take on extra supplies beyond the permissible stock limits imposed by the fuel authorities, and only the very rigid embargoes in force prevented them from doing so. Now all this is changed. The average steam-user is quite content with his present reserve and is indifferent to coal shippers who plead their good service under other conditions in order to move coal for which there is today only a restricted and dull market.

One of the natural consequences of such a situation is the number of cancellations of contracts entered into in good faith last spring and for the most part through regular channels. In the great anxiety to get shipments forward many buyers availed themselves of the service of the Fuel Administration, especially during August and September, not foreseeing that the same reasons which made possible volume shipments through the fuel authorities would shortly make way for similar deliveries through trade channels. The net results is that many consumers have had their storage so completely filled with coal requisitioned by or through state administrators that they are now utterly unable to take on deliveries due them on contracts from shippers and distributors who have been their regular sources of supply.

While the number of loadings for New England are much less than normal, the present dispatch at Hampton Roads is more satisfactory than for several weeks. Barges recently at the piers for New England destinations have been detained but three or four days on the average. For reasons already stated it becomes more and more of a problem to place cargoes at this end, even where choice grades of Pocahontas and New River are concerned, and storage at the various rehandling plants is being taxed to capacity. Distributors who are without such facilities are obliged to allow the coal to move offshore or on Government requisitions.

Coal that latterly has been moving to Mr. Storrow's order at the Baltimore piers has now been shut off, it is understood, because the placing of it at this end caused increasing embarrassment. Similar action is likely to be taken soon with respect to "Storrow coal" at Port Reading and South Amboy. Even on Long Island Sound it is difficult to find buyers willing to accept water deliveries on current freights while all-rail coal can be had as freely as now. Those with regular connections are finding no difficulty at all in getting rail coal forward from regular sources of supply.

Receipts at the five New England gateways continue to show a marked falling off The October daily average, railroad fuel included, was 507 cars, but the average daily movement for the first five days in November was but 438 cars, both commercial and railroad supply coal having dropped off to a notable extent. As compared with the month of August present all-rail receipts of bituminous are but 58 per cent.

The railroads in this territory are particularly well stocked. Both the Boston & Maine and the New Haven have reserve supplies in excess of those a year ago and correct receipts are more than ample. In many cases contractors have been urged to place the coal elsewhere, so assiduous have the fuel authorities shown themselves to dump coal on the railroads. A large number of cargoes have been absorbed in this way that would otherwise have found market only with greatest difficulty. Certainly the operator who looks in this direction to keep his mine running at the present pace through January, February and March is headed for disappointment.

It appears that prior to Oct. 1, receipts of bituminous in New England were but 15,897,748 net tons, against the 18,000,000 net tons agreed upon last spring as a six months' quota on the basis of 30,000,000 net tons for the 12 months from Apr. 1. In other words, this territory absorbed 2,100,000 net tons less than quota during the first six months. Add to this the receipts for October, about 1,330,000 tons, and every nook and cranny has been stuffed. There were many coal men last spring who believe that New England's requirements were being overdrawn, and the outcome proves the correctness of their position.

Anthracite—Very little change is noted in the receipts of anthracite. The October average all-rail was 414 cars daily of domestic sizes, while for the first five days of this month the average was but 359. It is fair to say, however, that this latter period included coal started from the mines during a week of generally light production. Water deliveries are somewhat improved. New York loading conditions are better than during October, although the proportion of stove and chestnut is still small.

The surplus of broken and pea continues an awkward problem for retail dealers. An order of the Boston Fuel Committee was issued Nov. 4 recognizing an oversupply of these sizes and directing that until further notice each sale and delivery of egg should include an equal quantity of broken, and each sale and delivery of stove or nut should include an equal tonnage of pea. Could this be carried out in every case it would doubtless be a distinct help, but there are dealers who have less broken and pea than other sizes. Moreover, there are cargoes of stove and chestnut or all chestnut coming forward on special requisition to be distributed through local boards, and the dealer who insists upon mixtures including pea coal is promptly reminded that lots of straight stove or chestnut can be had for the mere asking. No army officer or fuel authority anywhere but always takes pains to requisition stove and chestnut, leaving other sizes to the rest of the community.

NEW YORK

Anthracite receipts far below requirements, and consumers are urged to use the smaller sizes wherever possible. Fuel Administration allows retail dealers to increase prices 95c. Mayor Hylan told to stop survey and keep hands off. Dumpings show decrease. Bituminous in good shape, with coal moving freely.

Anthracite—Receipts of domestic sizes of anthracite continue to be just about enough to meet immediate requirements. No dealer receives sufficient to take care of the needs of his customers while nearly all dealers have more than enough Buckwheat No. 1 and the smaller coals than they require.

The new price schedule announced on Nov. 7 was a surprise to some producers and shippers who looked for a larger advance in view of the wage increase granted the mine workers. While the operators are given an advance of $1.05 per ton at the mine, local retail dealers have been permitted to increase their delivery price 95c. per net ton. The new price will not affect those who buy in 100-lb. lots or less; who will continue to pay at the rate of 60c. for 100 lb. when the coal is called for at the peddler's cellars and 70c. for 100 lb. when delivered at homes. In yards or coal pockets with facilities for handling coal rapidly small consumers will be able to buy coal at 55c. for 100 lb. on the cash-and-carry basis.

Dumpings of anthracite at the local docks for the week ended Nov. 8 show a falling off from the figures for the previous seven days. The reports show that there were 4997 cars dumped as compared with 6425 cars the previous week, a decrease of 1328 cars, a considerable number with conditions as they now exist.

The local situation has been aggravated some by a strike of men employed on railroad tugs. Upward of 800 men quit work and refused to go back until the Federal authorities intervened and promised the strikers arbitration of their demands, one of which was an 8-hour day. While this trouble existed shipments were further delayed by a strike of coal loaders at some of the docks.

There is no stove or chestnut coal to be had and a small tonnage of egg is available. Broken and pea are in fairly good shape and consumers of the domestic sizes are being urged to use either Buckwheat No. 1 or the smaller sizes of anthracite by mixing them with the larger coals. However, the situation is not alarming. The dealers are not being urged to make deliveries, which only makes stronger the belief that consumers are well supplied.

The allotment of domestic sizes for New York City of the 1918-1919 season has been reduced 4557 tons according to an announcement made last week, which leaves the allotment now at 8,001,418 tons. This deducted tonnage, together with deductions from other communities throughout the state, will be divided among other towns and cities in New York State.

There is an abundance of Buckwheat No. 1 and the smaller coals to be had. Household consumers are being educated in their use. Rice is not so much in evidence as buckwheat, barley or culm.

Mayor Hylan, who ordered the Police Department to make a coal survey of the factories and homes in Greater New York, received a rebuke when he received a telegram from Dr. Garfield to stop interfering with the distribution plans of the Government. The Mayor was informed that State Fuel Administrator Cooke was in charge of the coal situation here. The Mayor's plan did not find favor with Mr. Cooke or the trade, and the former took the matter up with Dr. Garfield. However, despite Dr. Garfield's telegram the police started the survey.

Current quotations, per gross ton, f.o.b., tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individual
Broken	$7.80	$8.55	Buck	$5.10	$5.90
Egg	7.70	8.45	Rice	4.65	5.10
Stove	7.95	8.70	Barley	4.15	4.30
Chestnut	8.05	8.80	Boiler	4.60	
Pea	6.55	7.30			

Quotations for domestic coals at the upper ports are generally 5c. higher on ac-

count of the difference in freight rates. Prices in Buckwheat No. 1 and the smaller sizes of anthracite coal are not fixed by the Government.

Bituminous—The peace rumors have had a telling effect on the bituminous situation. With the market apparently well supplied and the New England situation in good shape, shippers are looking into the future, while consumers are not anxious to have large shipments added to their stocks already on hand. There is a sufficient supply of commercial coals here for all immediate needs and manufacturers are more particular now as to what they receive than formerly, inasmuch as most of them have good sized stocks on hand.

With the discontinuance of Lake shipments this week and the reported decision of the New England Fuel Administrators that those states can get along with more than two million tons less coal than was originally allotted to them, shippers see the market overstocked with coal within the next few weeks unless weather conditions become such as to cause a heavy consumption.

Current quotations, based on Government prices at the mines, net ton f.o.b., tidewater at the lower ports, are as follows:

	Mine Gross	F.o.b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite price increase announced. Delay of week causes dealers to lose. Retail prices increased. Receipts at very low ebb. No stove or nut for sale. Mild weather helps the situation. New zoning system coming. Steam coals quiet. Some washeries shut down. Bituminous easy. Better grades still scarce. Lower prices likely on some grades.

Anthracite—The increase of $1.05 per ton in the mines prices of coal has now gone into effect. Owing to the increase dating from Nov. 1, and not being announced until a week after that date, the retail men have suffered quite a loss. It is true the shipments have been light, and it looks as if the shipping companies were endeavoring to help out the coal men by giving them as little coal as possible. The retailers were in the peculiar situation of wanting coal very badly yet afraid they might get it, with the consequent loss in the retail price.

Everywhere the question is asked as to the cause of the delay between the time of announcing the wage increase and the new mines prices. All sorts of rumors are afloat, and one most frequently heard is that the variance of opinion between the operators and the Government as to the new prices was such at times that only a threat to go before Congress and ask for Government control of the mines finally induced an agreement. Another serious point of contention was the individual differential of 75c. A number of the smaller operators claimed that without this difference they would be compelled to close their mines. Once more they have won their point. Another report is that the Government put forth a plan to pool all coal and then distributed at a flat price.

With the new wholesale prices in effect from Nov. 1 representative retail prices are about as follows.

	Egg	Stove	Nut	Pea
Company shipments	$10.25	$10.50	$10.60	$9.00
Individual shipments	11.00	11.25	11.35	9.75

Broken coal also shared in the increase, but as the tonnage of this size used in the domestic trade is negligible it is not deemed worth while to quote on it. All of this coal is made on special order and sold for manufacturing use and buyers will of course be compelled to pay the $1.05 over the old circular of $5.95 for company coal and 75c. increase for individual shipments.

The trade has never before gone through a week similar to the present. It has been many months since the receipts have been so small. The stocks in the yards are also at a low ebb. The city is practically without stove and chestnut, except, of course, what is stored in the bins of the householders.

In a day or two the new zone system as worked out by the local fuel administration is to be announced to the shippers. It appears that this city's increased quota is not to be divided proportionately among the dealers, but to each zone, the zones being designated by a number.

The steam coal market is not strong by any means and there are some who claim the recent loss of that tonnage due to the idleness of the mines on account of the epidemic is all that saved the situation from becoming serious to some shippers. Some operators report buckwheat comparatively free and none can be found who will say that it is scarce. All seem fairly comfortable on rice. Barley and culm are a dead issue. The washery and river people are at their wits' ends and many have ceased work. The market for spot coal for the latter two sizes is so poor that when orders are not in hand and operators have no storage capacity, it is being thrown on the banks.

The prices per gross ton f. o. b. cars at mines for line shipment and f. o. b. Port Richmond for tide are as follows:

	Line	Tide
Broken	$5.95	$7.30
Egg	5.85	7.20
Stove	6.10	7.45
Nut	6.20	7.55
Pea	4.80	6.05
Buckwheat	3.40	4.45
Rice	2.90	3.80
Boiler	2.70	3.70
Barley	2.40	3.30
Culm	1.25	2.15

The foregoing prices cover company coal. Individual shipments on sizes broken to pea inclusive are 75c. higher. Steam sizes are sold at market prices.

Bituminous—The situation continues to be very easy. Plenty of coal is reaching the market. As is to be expected, the better grades are hard to get and some concerns are now in position where they will only take the quality suited to their particular need. As yet there seems to have been no deviation from the Government prices, but if open weather continues for any great length of time there is no reason why sales should not be made less than the Government price. At least that is the expectation in some quarters, as some grades are even now finding difficulty in making the market at the full Government figure.

BALTIMORE

Receipts of bituminous light, but little feverish anxiety is shown by consumers, who seem to feel that the end of the war will in some strange way bring relief. Hard coal scarce and people turn to substitutes.

Bituminous—While the receipts of bituminous here continue below normal, despite the effort of the Baltimore & Ohio R.R. to increase the haulage by assigning additional locomotives to the coal fields, the consuming public has assumed a sudden new attitude. Although many industries are seeing their small stocks constantly dwindling, the best posted coal men here say there is no excitement over the prospects of a serious shortage, and that many consumers are looking for the sudden termination of the war to bring them relief all at once in some mysterious manner.

During the past week the jobbers here continued to discuss the ruling which gave mines a right to bill direct on requisitioned coal, and a new phase in a supplemental order which will allow such mines to collect a reconsignment charge of 15c. a ton, while refusing them the right to collect the 15c. as a jobber's commission. The fact that the order then provides that any mine charging 15c. a ton for rebilling will automatically cut out the collection of a jobber's commission by anyone also stirred the trade. The executive committee of the national jobbers was summoned to Cleveland to discuss the situation.

A local feature here the past week was an embargo against the Canton coal pier for three days because shipping board and local public service corporation coal had clogged the terminal. During that time the harbor trade, which had no coal on hand, was hard hit by the embargo.

Anthracite—Hard coal continues scarce. The fact that the trade here is not getting enough hard coal and is not even getting the high-grade lump bituminous as a domestic substitute, as promised and urged by both the local and national fuel administrations, is causing a search for other substitutes. Among the latest is a call for reclaimed coke. Several dealers have already taken up this idea and through it may come some measure of protection to the small half ton, peck and bushel trade, which is without coal for the most part and with little prospect of getting any such fuel.

Lake Markets

PITTSBURGH

Lake shipments practically finished. Spread of influenza checked. Market firm.

Last week practically concluded lake shipments of coal from the Pittsburgh district, there being only a little belated movement this week. If it had not been for the extra demands made on the district since July, it would have been possible to complete the district's quota, as originally set, by about Oct. 15, and the coal thereby released could have been used for stocking purposes. The coal lately released from the lake movement is being distributed to essential industries and to railroads and to "semi-essential" industries. For several weeks past there has been an increased supply to retail dealers. On the whole the coal situation is a fairly satisfactory one, provided there are no great transportation difficulties in the winter.

While the full effects of the influenza epidemic are still felt in curtailment of working forces, the situation as to the progress of the disease is regarded as decidedly promising. The matter is well in hand now, with a fair supply of medical help and nurses. Much of the present absence of workmen is attributed not to their having the disease, but to their having sore arms from inoculation or to their having sickness in the family. Production is about 40 per cent. below rated capacity, based on full labor and car supplies, but the curtailment from rates previously attained is much less. Maximum production of the Pittsburgh district averaged about 1,150,000 tons a week and it is estimated, in advance of specific reports, that production is now running but little under a million tons a week.

BUFFALO

Bituminous plenty. Prospect of no further shortage. Jobbers taking courage, for free coal is appearing. Conditions at mines improving. Anthracite still scarce. Lakes close early.

Bituminous—The appearance of more and more unsold coal on the market has given consumers courage. The war situation has held up buying, as purchasers expect prices to go lower. This will surely be the case if the jobbers continue to get telegrams offering coal at the mines. Grain men say that wheat would drop to a low price if it was not held up by Government, so coal shippers and especially consumers are asking if the same is not likely soon to be the case with coal. While the over supply of coal is not large, it is ample enough to make a change in market conditions.

Already the Government has dropped the zone restriction which kept Ohio coal away from Buffalo, and there is a rumor that all zones will be given up so far as the bituminous trade goes. This encourages the jobbers, who are never wanted unless there is a shortage. Telegrams are coming in from the mines, asking jobbers if they cannot dispose of loaded cars of coal for which there is no consignee.

Anthracite—The conditions do not change. Consumers are demanding coal which the distributors are unable to provide. The apparent shortage is likely to continue most of the winter, for nobody will be satisfied until his whole winter's coal is in. When the lakes are closed the supply is likely to be increased materially, but as this is not assured the consumer is anxious. Buying of bituminous lump and anthracite buckwheat is increasing, as together they can be used in a furnace if handled properly. The work of the local fuel administrators is almost entirely confined to the anthracite trade. All industries and others that can use soft coal are directed to do so, and the entire anthracite supply is turned into the house trade.

CLEVELAND

Although the influenza epidemic has abated considerably in eastern and southern Ohio coal-mining regions, car supply continues in excess of demand. The Great Lakes season has been shortened 14 to 21 days, but in spite of the earlier closing the Northwest will get every ton of bituminous desired. Decreased lake shipments are making up for lost production. Bituminous for industrial and domestic purposes becomes more plentiful every week.

Bituminous—Talk of peace has served to narrow the local coal market, but except under out-of-the-ordinary conditions prices have not sagged under the Government maximum. A few small blocks of low-grade coal—probably not more than five or six—have been marketed here in the past few days at 50 to 75c. a ton under the maximum. As against this, several operators report good-sized sales of high-grade No. 8 coal at the full Government price.

The consensus of opinion among better informed operators is that demand for coal will show a marked and steady decline from now on, but that prices, while sagging, will not break. Not much of a reduction is anticipated for months, in fact.

Labor, operators point out, has a scale that will not expire until April 1, 1920. Railroad rates cannot be expected to be reduced much, if at all, for some time. Only in supplies can lower costs be looked for. The upshot, with decreased demand and continued high cost of operation, it is feared, will be closing of the less efficient mines and about three-day-a-week operations at the larger and better manned mines until the period of readjustment is passed. Some operators hope that a larger export coal demand than foreseen will tide them over. Others are urging that once the present maximum Government prices are removed—they figure they die legally at the technical ending of the war—the Government institute minimum prices for a while.

Anthracite—Anthracite coal conditions seem even worse than usual in contrast to the greatly improved situation in bituminous. Receipts have dropped from 75 to 90 cars a week to 50 to 60. Lake shippers are making more complaint than retailers, for the Northwest's quota is not more than 60 per cent. net, it is claimed.

Lake Trade — The unexpectedly early peace movement which, with the lack of ocean tonnage, has eliminated the planned late lake season, has pushed the end of the lake coal season even nearer than first apparent, and every move of the lake trade now is made with the view of ending shipments Nov. 23. Some coal will be dumped after that date, but the pooling operations will not take care of it and the shipper must take care of it at both ends of the route. The official statement of the Coal and Ore Exchange, of Cleveland, which has had charge of the Great Lakes pool, is that up to Nov. 1 the lower lake docks had dumped 25,633,000 tons of bituminous. This leaves 2,367,000 as November's share of the 28,000,000 tons wanted by the Northwest, and the month's quota on the schedule is only 2,400,000 tons. Coal is coming forward much slower, and the dumping is at the rate of not over 900,000 tons a week. How much better the Northwest's coal has gone forward this season can be seen from the total of 1917 shipments—only 26,828,759 tons for a season that extended until the middle of December as against 25,633,000 tons for this year up to only Nov. 1.

DETROIT

Inquiry from buyers has eased off very materially in the steam trade as well as in thecase of retailers. Anthracite is still sought. Lake trade is shrinking.

Bituminous—Inertia seems to have become a prominent feature of the coal trade in Detroit in the last few weeks. Buyers who were clamoring recently to be supplied with coal now appear to present an attitude verging on indifference. The situation affords little encouragement to jobbers and wholesalers, whose efforts to stimulate business are only moderately successful.

Industrial plants and the larger users of steam coal seem to have accumulated stocks as large as they care to hold at this time, and the situation as regards buying by retailers is almost the same. Jobbers say that both the retailers and the steam coal users have been following the advice of the Fuel Administration in stocking any kind of coal obtainable and have not always bought with discretion. The result is many retailers have heavy stocks of mine-run and are finding their customers want something else, while a good deal of domestic lump and other prepared sizes is distributed about in storage piles of industrial plants.

Anthracite—Despite the increase in receipts of anthracite in October, distribution of an initial allotment to household consumers is still far from complete. Several thousand baseburner owners are still waiting for the two tons allowed them as the maximum for starting the winter. Complaint is made that many owners of hot-air furnace heaters are holding back apparently in expectation of getting anthracite, without taking the bituminous, which the Fuel Administration makes obligatory.

Lake Trade—Vessel capacity for movement of coal to the head of the lakes is being offered in greater amount than can be accommodated by cargoes. The close of the coal shipping season is forecasted for about Nov. 23, though one large shipper is reported to be planning a later movement, providing ships are obtainable. Soft coal shipments through St. Marys River canals in October amounted to 3,193,378 tons, a new record for one month.

COLUMBUS

With the report that Germany has signed the armistice and that the war is practically over, coal men are looking about to see what will happen. The demand for steam tonnage has been curtailed to a large degree. The lake trade will soon be over.

Operators as well as jobbers believe that the war is now entirely over, except the signing of peace, and as a result the change back to normal conditions will start soon. As a consequence there is a considerable amount of mine-run and screenings on the market. All buyers are limiting their orders because of retrenchment which has now started in earnest. Lump is not so badly affected as mine-run and screenings, as dealers are still in the market for prepared sizes.

Little is doing in the domestic trade as warm weather still curtails orders from householders. Retail stocks are generally good, and many dealers have their storage capacity filled. Retailers are not inclined to buy any more mine-run but are waiting for the so called fancy grades. Stocks in the bins and cellars of consumers are larger than ever before at this time. Retail prices still continue firm at Government levels. Pocahontas is not to be had but there is a larger amount of West Virginia grades arriving.

Some cutting of steam prices is reported, but it is not yet sufficient to demoralize the market. Thin-vein Hocking prices for mine-run and slack are now the same as thick-vein prices, as the 40c. differential has disappeared. Most of the steam plants have stocks to last from six weeks to three months and possibly longer.

The lake trade is still active but indications point to an earlier closing than usual. An unofficial statement fixes the date for the last cargoes to leave lower lake ports at Nov. 23. It is known that requisitions for lake shipments have been generally filled and the Northwest will be fueled.

CINCINNATI

Mild weather has kept down demand, while the influenza has hampered production. Improvement in both respects is expected shortly.

With only one or two frosty nights, the weather continues to be unusually mild for so late in the season, especially after so warm and pleasant a month as October was; and the unexpected phenomenon of a weather market is therefore in evidence, in the face of the general prediction that demand would be in heavy volume during the entire season.

Much of this is due unquestionably to the fact that domestic consumers stored their coal during the summer to an unprecedented extent, so that demand from this source did not amount to much with the first cool weather; while the requirements of heating plants burning steam coal have likewise not been up to a normal volume, both on account of the mild weather and on account of a fair degree of storage accumulations. This, on the whole, has of course been extremely fortunate, because it has permitted the available supplies of fuel to go to essential industries; while, on the other hand, the continued prevalence of influenza in the mining districts has so limited production that had a heavy demand been experienced there would very probably have been a shortage.

Transportation has also been hampered for the same reason, although the supply of cars has been well up to the production at the mines, reduced as indicated. Lack of facilities in the mining districts for caring for large numbers of sick has prolonged the epidemic beyond the period to which it went in the cities, and as it also started later in the remote districts, it will run correspondingly later. Frosty weather and the natural course of the disease are expected to see the finish of the epidemic shortly, however.

LOUISVILLE

Market generally supplied, with demand for all grades of coal draggy, in spite of low production at the mines of less than 50 per cent. of the average year's production.

The coal business is generally dull with producer, jobber and retailer at the present time, there being practically no demand for steam grades or domestic coal. Industrial consumers appear to be well stocked, and not interested in buying, many holding back due to the peace news, which has unsettled the market as some cancellations of war contracts have been reported. Mild weather has resulted in little demand for domestic coal. Local retailers report a month's supply of lump roal on hand, and many are beginning to advertise rather extensively for business. There is a fair demand for the better grades of eastern Kentucky lump, which has been scarce all season due to the fact that producers have been mining and shipping mine-run.

A general report is to the effect that the Northwest and Lake district is loaded up, while Indiana, Ohio and Kentucky appear well stocked. The South is also well taken care of. Local jobbers report that there is no demand for Indiana coal in that state, western Kentucky coal shows a general surplus, while mine-run eastern Kentucky is also representing a surplus, there being plenty of all grades of Hazard and western Kentucky coal on the market. It is reported that other close-by markets are in the same shape, with surplus stocks on hand and no outlet.

A number of eastern Kentucky mining companies will be forced to go back to screening coal again in order to secure a ready market for lump coal, which will sell. However, how they will dispose of the screenings with the market overstocked as it now is represents a serious question.

With normal production the situation would be much more severe. However, influenza is still holding back operations in all sections of the state, there having been but little improvement shown at some points, with the result that production at the present time is between 30 and 50 per cent. of what it has been for the greater portion of the year.

BIRMINGHAM

Market conditions quiet. Demand for higher grades of steam coal fair. Domestic coal scarce, with strong inquiry. Production slowly recovering from the effects of the influenza epidemic. Transportation facilities adequate.

The market for the lower grades of steam coal is rather soft, but there is a fair demand for the better quality of this class of fuel, such as Black Creek and similar grades, and all in all trade requirements are about equal to the production, which is still far below the output maintained prior to the siege of sickness in the camps.

Domestic coal is a very scarce article and a large tonnage of regular steam product is being diverted to domestic dealers for use in filling orders in hand. Many yards which normally had large stocks on hand at this season are practically bare and are dependent on daily receipts to fill orders.

The Brookside-Pratt Mining Co. will shortly resume operations at Carbon Hill, which is a stripping operation on the Jaeger seam, work having been suspended there for several weeks while equipment was being shifted to another tract. The New Castle Coal Co. is preparing to reopen the old No. 4 Mine, at New Castle, and the necessary mine and railroad tracks are now being installed.

Coal production for Alabama for the week ending Oct. 26 was 310,041 net tons, the lowest mark reached since the Government has been recording the output. Sickness has about disappeared from mining camps now and a steady gain is being noticed in production, though several weeks will likely elapse before conditions become normal.

Coke

CONNELLSVILLE

Production continues to decline, but bottom believed to be passed. No great coke shortage. Fuel Administration could fix minimum coke prices.

Production of coke in the Connellsville region and shipments of raw coal have continued to decline, by reason of the epidemic of influenza, but the bottom is now believed to have been passed and rising production is expected to be reported beginning with this week. From the maximum rate of coke production reached this year, which was early in September, the drop has been about 15 per cent. Maximum raw coal shipments were reached early in October, and the decline there has also been about 15 per cent.

Several byproduct interests whose coal receipts from the Connellsville district have been decreased have applied to the Pittsburgh district coal distributor for relief, but except in minor instances it has been impossible for the Pittsburgh district to help out in this manner, as its own production has been curtailed by the epidemic.

Blast furnaces do not appear to be suffering seriously from lack of coke. Pig-iron production in October as a whole was at a rate 1.3 per cent. less than the rate in September, this being attributable in part to influenza among blast furnace workmen and to various other causes, including a few cases of coke shortage.

The final cessation of hostilities will not directly affect the price limit on coke

While pig iron and steel prices generally are set by the War Industries Board, through agreement with the producers, and are reconsidered each quarter, the coke prices are set by the Fuel Administration under the Lever act, and the full powers of the Fuel Administration continue until the President issues his peace proclamation. The Fuel Administration can reduce the present maximum limits, and the law would even seem to give it full power to set minimum prices. This is a matter of interest at this time, seeing that there is now much talk in the iron and steel trade as to the desirability of the Government regulating iron and steel prices generally on their downward course from war time to peace time conditions, so as to avoid a slump. If there were such regulation in iron and steel there would naturally be regulation in coke also.

With decreased production there is no chance of furnace coke coming into the market and offerings of foundry coke have decreased. Offerings of coke screenings from old dumps are about as formerly. The market remains quotable at the set maximum limits, as follows: Furnace, $6; foundry, 72-hour selected, $7; crushed, over ¾-in., $7.30; clean screenings, over ½-in., $5.50, per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Nov. 2 at 293,865 tons, a decrease of 8529 tons, and raw coal shipments at 216,237 tons, a decrease of 18,280 tons.

Buffalo—The market is easy and on a par with the bituminous trade. Furnaces are getting all they want and are not obliged to search for coke as they were awhile ago. This district is depending almost entirely on byproduct supplies. More ovens will be put in as soon as they can be built. Fuel coke is more plentiful, and if the price of coal declines, as one dealer already declares it has done, it will not be easy to sell breeze coke at all.

Middle Western

GENERAL REVIEW

No improvement in general market conditions. Operating conditions good. Buyers holding off in hope of a break in the market.

There is no noticeable improvement in general market conditions. As has been the case for over six weeks, however, the higher grade Illinois and Indiana coals remain fairly firm at Government price, but the poorer grades are offered freely at a discount from the Government prices. The mild weather is hindering any improvement in affairs, and orders throughout the territory are being cancelled as readily and as rapidly as they were being placed two or three months ago, when coal was hard to buy.

Operating conditions are good, and fair average tonnage will be produced from the various fields. The influenza is on the wane, and within a few days, at least, will cease to be a factor in the market or the industry, so far as the producing districts of Indiana and Illinois are concerned. The labor supply continues fair, without any radical changes, and will continue so until the cessation of fighting in Europe, after which, no doubt, there will be an improvement. The car supply is more than ample to take care of the requirements of the Mid-West district. To make sure, however, that there will be plenty of cars, one of the big railroads in this territory has discontinued giving empty coal-carrying equipment to the many stone quarries and gravel pits on its lines, and is concentrating these cars at the coal mines depending upon it.

The situation on Eastern coal, brought into the territory via the Great Lakes, is worth mentioning. The concensus of opinion is that in the spring the average dock company will have on hand a considerable tonnage of Eastern coal still unsold. This opinion is backed up by figures from one of the largest railroads serving the docks on the Northwest Lake district. These figures show a decrease of 3000 cars below last year's figures, and the decrease is growing daily. The explanation for this is that a lot of business heretofore going to the docks has been taken by the Illinois and Indiana operators.

So far as the outlook for the immediate future of the coal industry in this district is concerned, not much relief is to be looked for. The few that might perhaps be in the market are holding off, as they believe that the war will be practically over in a very short time, and they are gambling on the idea that there will be a further break in the market as soon as hostilities cease.

CHICAGO

Steam market continues weak. Mild weather has eased up domestic demand. Anthracite situation continues to arouse criticism.

One or two large buyers of steam coal were in the market this week, tempted by low prices rather than any actual need for coal. These purchases were not on a large enough scale to make any material difference in the steam market, which continues weak.

The domestic trade is still a weather proposition, and as a consequence there has been little buying for the past week. As soon as the mild weather stops, there no doubt will be a big improvement, as there has been so little buying on the part of the retail coal dealers that of necessity their coal stock must be reduced to some extent.

The anthracite situation still continues to call down upon the State Fuel Administration the wrath and disgust of the retail trade. From a source considered reliable, it was learned that there is a big tonnage of hard coal in Chicago proper—in fact, about enough to supply the average demands of the city. Irrespective of this, the anthracite cannot be marketed until the many rules and regulations of the local administration have been abrogated.

MILWAUKEE

Coal yards will enter the winter with shorter stocks of anthracite than last year. Dealers looking for an advance in prices. Deliveries of one ton to each consumer ordered.

The coal situation at Milwaukee, while not altogether satisfactory, admits of little fear of a serious famine. The prevalence of mild weather lessens the early fall consumption and contributes to the serenity of those who are still unsupplied with fuel for the winter. There is an adequate supply of bituminous coal, but stocks of anthracite are short when compared with this time last year, the leading dock company being about 150,000 tons behind in this respect. There are still about four weeks of lake navigation left, and it may be that the anthracite situation will be materially improved before cold weather sets in.

A sharp turn downward in temperature is bound to precipitate a stampede on the part of the fuelless, and, to forestall distress, State Fuel Administrator Fitzgerald has ordered dealers to deliver at least one ton of anthracite to each consumer before cold weather sets in, and to follow up the one-ton allotment in rotation and in such quantity as will keep every consumer supplied all winter. Parties using magazine heaters will be given preference over those having hot-air furnaces.

There seems to be a shortage of small sized anthracite and dealers are compelled to substitute egg size for the major part of all nut and stove size orders. The fuel administration advises consumers to break the coal to the smaller sizes if it is impossible for them to burn egg.

Prices current during the latter part of the summer and early fall are still in vogue, but dealers are expecting an advance in conformity with the recent increase in the wages of miners.

October's coal receipts aggregated 98,511 tons of anthracite and 393,252 tons of bituminous, making the receipts for the six months beginning with May 559,939 tons of the former and 3,161,129 tons of the latter. Thus far in November cargo receipts aggregate 25,203 tons of anthracite and 56,257 tons of bituminous.

ST. LOUIS

A continued quiet market, with no favorable weather conditions. A surplus from all fields and prices shot to pieces. Steam and domestic, both country and city, at a standstill and no storage coal going in. Railroad tonnage fairly good. Equipment and transportation good.

The local situation still continues to be an unsolved problem. The prevailing mild weather has upset all plans for an improved market and there is no demand at all for any kind of coal. This is not local, but is general throughout the territory adjacent to St. Louis. The "Buy Early" campaign amounted to far more than anybody expected, and it is not fully known yet as to how it is going to affect business for the next five or six weeks. Domestic business in St. Louis is absolutely at a standstill, some retailers not having their equipment out more than one or two days a week and only part of it then.

Steam plants, and especially those working on war orders, are using up their storage coal, and all other plants are going into their storage coal rather than buy on the open market, inasmuch as prices are all cut now and likely to continue so for some time, in the opinion of the buyer.

This same condition prevails throughout the country towns, and the result is that mines in the Standard field are idle because they have no place to put the coal and the prices are cut to the point where it cannot be sold at much of a profit. Standard 2-in. lump is around $1.75 to $2 and screenings can be bought from $1.25 up. Mt. Olive coal is being cut in some instances, but as a rule is holding up to the $2.55 price for the screened sizes.

In the Standard and Mt. Olive fields the bulk of the coal moving out now is for railroad uses, and this continues good. There is, of course, a decreased production at the mines that are working exclusively on railroad coal on account of the influenza epidemic, which still continues unusually severe in some mining towns.

The scarcity of water that has existed for some time past was relieved the past week by good rains. Equipment is plentiful and transportation good. A large tonnage of Mt. Olive coal, which has been moving to the north, is easing down.

Conditions in the Carterville and Duquoin fields forecast the catching up in the very near future with orders. The mines that have railroad tonnages are holding out best, but the mines working strictly on domestic coal are having a hard time right now. The northern market seems good, but the southern market is gone.

Considerable Carterville coal has been offered in the St. Louis market, and in order to move some of it it has been intimated that the Government maximum of $2.55 would be cut. In the face of this, however, St. Louis is not buying. No coal is moving in and there is no need of it. The dealers are stored to their capacity. Equipment is fairly plentiful and transportation is good.

The inflienza epidemic still prevails in these districts and many mines are shorthanded although none of them at this time are idle on account of no orders and not likely to be so for some little time, anyway.

In the retail circles in St. Louis, the prices are being cut somewhat, but it is not general.

The wholesale prices are, with the exceptions, as noted:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.75	$2.55@2.75	$2.40@2.70
3x6-in. egg	2.55@2.75	2.55@2.75	2.40@2.70
2x3-in. nut	2.55@2.75	2.55@2.75	2.40@2.70
Washed:			
No. 1	3.05@3.20	3.05@3.20	.....
No. 2	3.05@3.20	3.05@3.20	.....
No. 3	3.05@3.20	3.05@3.20	.....
Mine Run	2.35@2.50	2.35@2.50	2.20@2.30
Screenings	2.17@2.32	2.17@1.32	1.50@1.60

Special preparation on Carterville is 10 cents. extra
Williamson & Franklin Co. rate is $1.10.
Other fields 95 cents.

SEATTLE

Vast amount of Western coal will supply South American countries which are furnishing this country with war supplies.

To expedite the shipments of Western coal to Chile and other South American countries, S. L. Yerkes, assistant general director of distribution for the United States Fuel Administration, is in this city making an investigation of coal mining and shipping conditions.

Coal will be exported to the Southern republics through Seattle, Portland and San Francisco if present plans mature. The coal passing through Portland will come from Utah and Wyoming, and shipments from the two states will also pass through San Francisco. The Washington and Montana shipments will continue to come through Seattle. Already 25,000 tons of Washington coal have been sent to Chile and other Southern countries. The Pacific Coast Coal Co. sent an efficiency engineer south with the first cargo, and his work in directing the change from the use of Eastern and Welsh coals is said to have been highly satisfactory. He showed the Southern consumers the most economical way to use Washington coal. There is no fixed amount of coal that must be supplied, but a great deal will be forwarded. Formerly Chile and other South American countries secured their coal from Australia and Wales. But the war cut that supply off and lack of shipping facilities and the needs in the Eastern states have cut that supply off. The United States is receiving nitrates from Chile and it is necessary that we keep her supplied with fuel. Shipping arrangements have been practically completed.

COAL AGE

Volume 14 New York, November 21, 1918 *Number* 21

Patriotic Duty of Buyers

By R. Dawson Hall

FINANCIAL troubles and lack of work arise in general from the inactivity of buyers, who make up their minds that prices are high and may soon drop, and then fold their hands and wait for the drop to come. As a result business drags till their prognostication proves true or false. Usually, however, if enough buyers wait, wages and prices actually do fall so as to make the delay profitable to the individual, though quite frequently he suffers more in the collapse that follows than he gains by the decline in price.

So far this delay has been regarded as justifiable except in the matter of labor purchases. A delay in buying labor on the part of an employer is known as a lockout, and is, in general, looked upon as being morally indefensible. Mines and manufactories may be closed down if the operation is unprofitable, or if the product cannot be sold, but it is considered reprehensible to close them down merely for the purpose of making the worker take less for his labor.

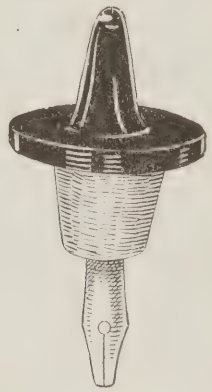
In this instance, then, we have ruled that the buyer has a duty to go on buying. He is not allowed to seek a reduction in the price of labor by closing down, but on the other hand he is permitted to refuse to buy the product of labor and thus cause all manner of idleness in the hope of lowering the price of the product and incidentally the wage rate. Eventually, we may class both actions as equally reprehensible, for they have the same result.

We may regard the conspiracy to refuse to *buy* goods, when that refusal is made for the purpose of lowering the price of the goods, as being morally as bad as a conspiracy to refuse to *sell* them, when that refusal is made for the purpose of raising the price above the market.

In law doubtless the conspiracies are equally illegal, but in common acceptance the attempt to lower a price by combination or by abstention from purchase is almost never considered wrong; and the law against it as a conspiracy is not pressed. The public has yet to be made to learn that there is a moral wrong done to the nation every time a man or a group of men delay purchases of material for which they have an actual need. Just what are the duties of the buyer cannot perhaps be set forth in black and white, but it is well for us to take a glimpse at his duties just at the present when conditions are so poised that a few days of inconsiderate and needless abstention from a patriotic duty may wreck the whole financial structure.

In the medieval era the buyer was quite generally a lord and the seller almost always a serf. From these earlier and simpler times we have inherited a viewpoint which gives us little respect for the seller and his rights. Nevertheless he should not be denied trade at the whim of the buyer nor, on the other hand, should he be berated by the would-be purchaser if he fails to supply in a few days on the demand of the buyer what the buyer, had he been reasonably forehanded, could, just as readily, have arranged to receive in installments spread over a period of months.

Patriotism demands of us all at this time that we buy what we want without unnecessary delay. It is well known that there is plenty of demand for labor and material, and any let up in work now must be followed by feverish anxiety to produce later. Why then have a slack period? Rather let us advocate as a patriotic duty, in so far as may be feasible, that "Business as usual" be the motto of the nation.



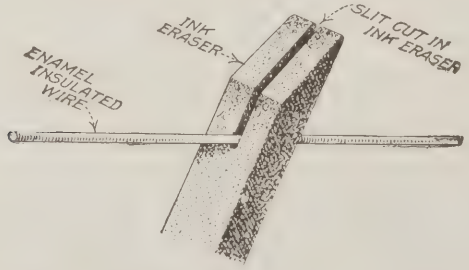
At any time a determination of the buyers to abstain from buying will wreck the market and cause immense distress. By his inconsiderate action the man who abstains from buying is almost as likely to hurt himself as others. Seldom is it advisable and never is it patriotic to hold off from such purchases as we would make at once if we were assured that the price would remain stationary.

IDEAS AND SUGGESTIONS

"Tip" for the Ink Bottle

BY J. A. LUCAS
Ozone Park, N. Y.

In many drawing rooms the draftsmen use small ink bottles that are frequently refilled from the larger ones in which the ink is purchased. These small bottles are thus used for a long time, and the quill which is attached to the stopper becomes soft, and sometimes



PRACTICAL FILLER FOR INK BOTTLE

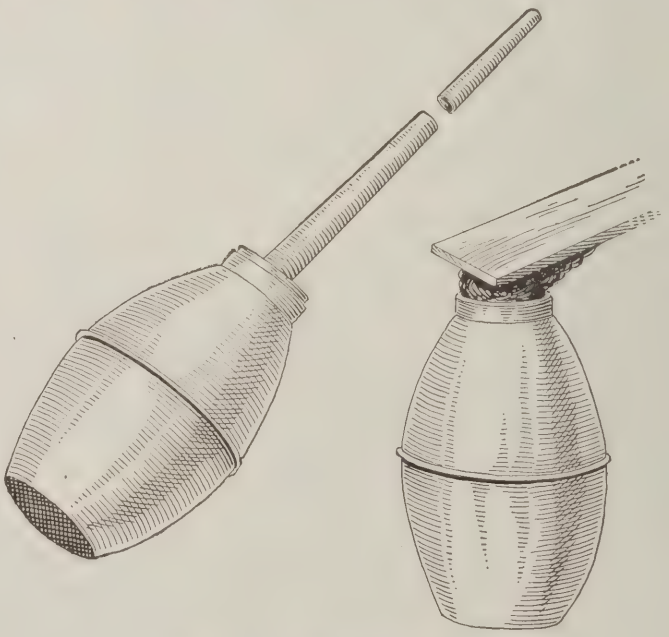
is broken, so that it will not reach to the bottom of the bottle. The broken quill may be cut off close to the cork and a large stub pen inserted so that the point will reach the bottom of the bottle when the stopper is in place. After this change has been made the filler will be found to give as good service as a new one and in addition will last considerably longer.

Removing Enamel Insulation from Wire

A scheme for removing the enamel insulation from small magnet wires without the aid of a knife, and one that has been found to work out satisfactorily, is shown in the accompanying illustration. Where this plan is

DEVICE REMOVES INSULATION FROM WIRE

used it is only necessary to cut a slit with a penknife in an ink eraser and then rub the eraser to and fro along the wire in different positions. This removes the enamel and does not nick the copper. It is not desirable to use a knife for this purpose because it will nick, mar or scratch the wire.



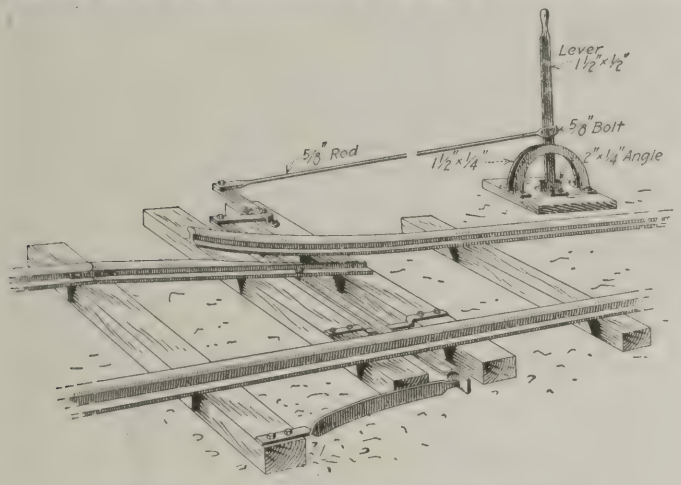
Material Needed in Mine Rescue Work

After many a mine disaster no progress can be made in recovery work without reëstablishing the ventilation. For this purpose much material may be needed. Some authority at the mine should at once arrange for the quick delivery of a supply of brattice cloth or canvas and 1-in. planks. Near-by mines and sawmills should be notified to send as quickly as possible such material as may be available. Mine supply stores should be reached by telephone and asked to forward at once by the quickest available method a supply of canvas or brattice cloth. The necessary timber for the support of stopings is usually on hand at all mines; it may consist of props, ties and wooden rails. Saws, nails, hatchets and hammers should be provided in abundance. —*Rescue and Recovery Operations in Mines.*

Grease Cup Filler

BY ERNEST SCHWARTZ
New York, N. Y.

Filling grease cups in places difficult of access and those on certain machine parts is often a tedious operation, which always necessitates waste of the lubricating material. To overcome this, the device shown in the accompanying illustration will be found practicable. It



EASILY MADE GREASE GUN

can be made at a small cost. A rubber bulb is fitted with a brass or copper tube of any length desired. The bulb can be purchased in any drug store. The operation of filling the bulb with grease is shown in the right-hand sketch. Graphite compositions and oils can be quickly and successfully handled in large quantity by this method.

Simple Derailing Device

By J. W. Powell
Nanaimo, B. C.

The derailing device shown in the accompanying illustration has been installed at the head of the slopes at Cassidy, B. C. It has proved to be simple and positive in operation and absolutely reliable at all times. In addition to a head block, which is placed on top of the knuckle and which in itself satisfies the requirements of the Coal Mines Act, the device shown was placed in operation as an additional precaution in the interest of safety. The device is placed just below the knuckle at a point sufficiently far away to allow for the

SIMPLE AUTOMATIC DERAILING DEVICE

taking up of the slack in the rope, all couplings and the rope being taut before they reach the derailing switch.

The switch operates automatically when the trip ascends, working back and forth with the aid of the spring as the cars pass over it. This actuating spring is a leaf from an ordinary wagon spring. When the trip descends, the rope rider holds the lever, which is located on top of the slope that closes the switch, until the trip passes over it. He then releases the lever, when it returns to the safety position, as shown in the drawing. This contrivance is cheap and simple and can be installed in a few hours when the parts are completed. In fact the trip was held up only 30 minutes when the changes were made. In general it should be installed between shifts, after hoisting is through for the day.

Liberty Coal

Everyone realizes that the coal mines are short of miners and other help, and that the country needs all the coal that can be mined. An idea is being tried at a mine in Johnstown, Penn., that has every indication of being a success. Many day men are necessary in the operation of a large mine, and all of them are anxious to make as much money as possible. The company in question has therefore set apart a few rooms that are being cut by a chain machine and the track laid by day men. The props are also set and the coal shot by day men. Every night two men who are willing to work this extra shift as coal loaders are detailed to each place. They receive the same wages as other loaders at a set rate of so much per ton or are paid by the average car.

This plan gives extra shifts to any day men who want to load coal and help the situation as it exists at present. I think that there are quite a few day men who would gladly take this means of helping out the country and increasing their earnings. This idea can be used at all mines where the setting aside of certain rooms will not decrease the output and where there are sufficient men to work at night or a few hours evenings to load the coal. It might also be adopted at mines where there are no machines. The men can in such a case both dig and load coal and get the pick price.

Alternating-Current Motor Trouble

An alternating-current motor connected to a pump developed a hot spot on one of the coils. This hot spot was confined to a section of the coil about 2 in. long at the point of the connection. The motor ran all right. The hot spot seemed to attain a certain temperature, which it did not exceed, the rest of the coil remaining at a normal temperature.

The coils in this motor consisted of two No. 13 D. C. C. wires in multiple. The connections were examined and proved to be perfect. On removing the insulation from the coil at the point of heating, it was found that one wire of the start of the coil was partly shorted with one wire of the second turn of the same coil. The result was that the current was partly shunted around this one turn of the coil, causing the heating referred to. After raising the wires and reinsulating them at this point, the motor ran without heating the coil.

This is rather an odd case of trouble, as a shorted coil in an alternating-current winding generally results in that particular coil becoming red hot in a short time, burning off the insulation and causing damage to the other coils if the machine is permitted to run any length of time. The only remedy is to cut the coil out of the circuit, remove it from the machine, then reconnect the leads so as to bridge the gap caused by the removal of the coil.

Useful Combination Tool

An ingenious combination of a hacksaw and a cross peen hammer is shown in the accompanying illustration. This combination is not only advisable for the sake of convenience, but also to relieve the tool bag of unnecessary weight. It will also conserve space. In

COMBINATION HACKSAW AND HAMMER

construction the device is simple, and the illustration is self-explanatory. The hacksaw blade is adjusted by means of the setscrew, which will move the arm around the fulcrum and in this manner either tighten or loosen the blade.

Surface Plant of the Orient Mine in Franklin County, Illinois

Designed To Operate Under Varying Conditions of Transportation, the Orient Mine Holds the World's Hoisting Record of 6008 Tons in Eight Hours—The Operation Embodies Some of the Latest Mechanical Ideas

ALL manufacturers aim to turn out their product with the least expense consistent with the best results. The production of domestic and steam fuel should be no exception. An old coal operator once said, "The more valuable a ton of coal becomes to our customers the more in the end will be the producer's profit." Progressive operators today continue to work along such lines, as witness the fine million-dollar plants of the successful coal men of Franklin County, Illinois. The infinite pains taken to place a superior article on cars for shipment is told in the following description of one of the largest coal-preparation plants of southern Illinois; it was designed, constructed and equipped by some of the leading engineers, structural men and manufacturers. The Orient mine of the Chicago, Wilmington and Franklin Coal Co. is one of the largest and most successful in the Franklin County field. This mine holds the world's hoisting record of 6008 tons of coal per day of eight hours. Furthermore the week's output (from Oct. 7 to 12 inclusive) of coal hoisted, prepared and loaded for shipment was 32,514 tons. The run by days was—Monday 4928 tons, Tuesday 5237, Wednesday 5482, Thursday 6008, Friday 5355 and Saturday 5504, or an average of 5419 tons per day.

The average output was higher than any single day's output of any other mine in the southern Illinois field and the biggest day—6008 tons—is the largest single day's output heretofore reported for any coal mine in

FIG. 1. GENERAL VIEW OF ORIENT TIPPLE AND RESCREENING PLANT—THE HEADFRAME AND ENGINE HOUSE IN THE CENTER

The small views at the bottom show recent additions to the tipple and the rescreener. Left, reprocessing plant in connection with the storage recovery system; right, rescreener overflow for stocking surplus screenings

FIG. 2. VIEW OF ORIENT TIPPLE, HEADFRAME, AND ENGINE AND BOILER HOUSE

any field—a splendid achievement. To raise the 6008 tons on Thursday, it was necessary to make 1452 hoists or an average of 181½ hoists per hour; this is a little better than three per minute all day. The mine cars average somewhat better than four tons of coal each.

As evidenced by the comparatively large output on Wednesday and Friday, there was no unusual preparation for a big daily record drive by having extra coal on the bottom, and so on, nor was there any unusual let down on the day following. The record was stated to be "simply the result of a day's run in which there were practically no delays in any department of the operation—738 men reported for work on this day." The comment in quotation marks is the modest reference, on the part of the Orient mine's management, to a record which coal men will recognize as the result of intelligent planning from the inception of the mine to such a time as the mine and tipple development reached proportions permitting this most unusual movement of coal from face to railroad car. A number of other factors also enter into this problem such as the driving force of those responsible for results at the mine and the character of the men cutting and loading the coal. The slacker board at the Orient mine might also furnish some interesting information.

During the month of October, 1918, 132,411 tons of coal were hoisted at Orient. If this monthly record is the average for the year, the annual tonnage of this mine would amount to 1,588,932 tons—an achievement which should be closely approached judging from recent performance. In this connection reference is made to production information given in an article descriptive of the underground workings of the Orient plant in the Aug. 22, 1918, issue of *Coal Age*.

The surface plant at this mine is distributed about the main shaft. Views of the main structures in this group are shown in the accompanying illustrations. The tipple, which is built for large tonnage production, is presented in Figs. 1 and 2 from different points of view. As the coal is dumped from the Olsen cages at the top of the headframe it is discharged into the tipple. Here it is either loaded as run-of-mine or it is screened and made into the sizes commonly prepared in Illinois. The separation into the seven different sizes takes place in the tipple proper (the building at the left of Fig. 1) or in the rescreening house (shown at the right in Fig. 1). At times of uncertain car supply, run-of-mine or any of the prepared sizes may be stored and treated later, and loaded from the storage pile into railroad cars either for shipment or for reprocessing in the tipple.

Considering the preparation of the coal in detail, treatment starts when the run-of-mine is discharged into the bottom dump weigh pan at the top of the tipple. From this pan the coal goes to a reciprocating feeder which sends the coal uniformly to the screens. These shaking screens are 10 ft. wide and produce the regular sizes, according to Franklin County practice, over 6, 3 and 2-in. round perforations. Coal dropping through 2-in. round openings goes to the rescreening house. The three sizes made in the tipple proper are: lump (all coal passing over 6-in. round perforations), egg (drops through 6-in. and passes over 3-in.) and nut (goes over 2-in. round perforations). These three sizes are cleaned of impurities on the picking tables which are shown in Fig. 3; in this illustration men are at work picking out impurities which are taken up by means of a pan conveyor to a refuse storage bin. The refuse conveyor is the middle one of the three shown in Fig. 3; on either side are the conveyor picking tables for coal. The refuse storage bin is shown at the extreme left in Fig. 1; refuse is loaded into railroad cars from this bin and is thus carried for disposal to some point where it will not interfere with operations.

The lump, egg and nut coal is loaded into cars by booms to reduce breakage to a minimum. When run-of-mine is to be loaded, a gate is opened in the bottom of the feeder hopper, which diverts the coal from the screens (at a point just above the feeder) and into a chute; the lower end of this chute is the large pipe shown in Fig. 2 emerging from the side of the tipple and passing across and down to a loading point over a railroad track. This chute is used both for loading run-of-mine coal for shipment and for running coal into storage, as will be described later. On all loading tracks there is a car retarder made by the Fairmont Mining and Machinery Co., of Fairmont, W. Va. This arrangement permits each car trimmer to operate his own car as it is being loaded. All degradation from lump, egg and nut is carried by drag conveyor to an elevator which delivers to the rescreener belt or slack car; this belt conveys all coal dropping through the 2-in. perforations on the tipple screens to the rescreening house.

The rescreening house is shown at the extreme right of Fig. 1; it is of the latest type. In this building the screenings through the 2-in. perforations are treated and separated into four sizes. The rescreener is fed from the tipple by means of a 36-in. Stanley belt, made by the Stanley Belting Corporation, of Chicago, Ill. This belt runs on Stephens-Adamson ball-bearing rollers carried on an inclined covered bridge, which is shown in the center of Fig. 1, and which runs from the lower part of the tipple to the top of the rescreening house. The four sizes made here are nut No. 2, or stove (through 2-in. round perforations and over 1¼-in.), nut No. 3 (through 1¼-in. and over ¾-in.) nut No. 4, or pea (through ¾-in. and over ⅜-in.) and No. 5, or carbon (through ⅜-in. perforations).

The screening equipment consists of a four-deck, balanced steel shaking screen, suspended by board hangers and operated by double cranks with side arm connecting-rods. The screens are operated by a 15-hp. variable-speed motor; normally they run at 130 r.p.m., but they can be speeded up if wet coal is encountered or if an excessive quantity of small sizes comes up on the belt. The only size cleaned in this building is the No. 2 nut. Provision is made for this by having the lower end of the upper screen extended to form a picking pan where the impurities can be picked out. This refuse is taken to a bin at the end of the rescreener house shown in the small lower right-hand illustration in Fig. 1. This bin has a capacity of one carload. Under the rescreener house are the coal-storage pockets or bins; each bin holds 150 tons of coal, which is loaded out over a lip screen. The degradation is carried by a conveyor into the boiler house.

Motor Drives Sometimes Prove Advantageous

A pertinent thought comes up in connection with the motor drives which operate the shakers, scraper and elevator lines about this plant. Individual drives have been advocated for years, and in many cases this is the only practical solution. However, where machines naturally arrange themselves in groups about a plant, a motor drive for each group is thought to be an advantage by some. A number of machines tend to have a flywheel effect on a motor drive. The effect of an overload on one machine or of another discontinuing operation is neutralized by the balancing tendency of the remaining machines in the group.

About two years ago it was decided to install a ground overflow storage and recovery plant of large capacity at the Orient mine. Such action was brought about by the uncertain supply of cars and the great losses in operation consequent upon failure of car supply at a time when the men were in the mine. It was thought that a storage and recovery plant would equalize car supply and prevent losses through shutting down the mine in the course of a day's run. Furthermore, it should equalize coal production on account of variation in the market demand. Such a plan was carried out

FIG. 3. INTERIOR OF PICKING SHED AT TIPPLE OVER LOADING TRACKS

and involves three distinct operations: First, ground storage, by which mine-run coal or lump, or for that matter any size of coal is run out into the storage pile. Second, a recovery system by which the coal can be picked up and loaded either into railroad cars as mine-run or be taken back and reprocessed in the main tipple. Third, rescreener overflow by means of which the raw screenings can be wasted in a stock pile on the ground and afterward be recovered and reprocessed over the main screen or in the rescreener house.

In carrying out the first operation, or ground-storage part of the plan, a low trestle was built on a piece of flat land about half a mile down the track from the shaft. This trestle is about 1000 ft. long and 10 ft. high. The company then purchased twenty side-dump cars made by the Western Wheeled Scraper Co., of Aurora, Ill.; also two Link-Belt locomotive cranes, equipped with 2-yd. clamshell buckets. The dump cars have a capacity of 25 tons each. These cars are run under the chute at the tipple and filled with mine-run coal, then a train load is taken by the yard engine to the trestle and dumped, after which it is returned to the tipple. The cars are run in two trains so that one train can be under the tipple all the time. When the capacity of the trestle is reached, the locomotive cranes rehandle the coal and pile it within reach of their booms.

In this way it is possible to store coal as rapidly as it is being produced at the mine, so that the plant can be operated without slowing down the operation. The storage yard is shown in Fig. 4; the trestle is on the left

and the crane is shown at work rehandling the coal, taking it from the trestle and piling it to the right.

The second feature, or the recovery system, is planned for a smaller hourly capacity than the storing of coal in the storage yard. It is limited first by the capacity of the crane which loads the coal directly into railroad cars, and second by the capacity of the reprocessing plant, by means of which the coal is conveyed to the shaking screens again. The reprocessing plant is shown in the small bottom illustration to the left in Fig. 1. In case the coal at the storage yard is to be reprocessed, it is loaded back into the side-dump cars; these cars are moved to a point just above the tipple and then dropped by gravity on a special track to the reprocessing plant. The cars in this train of loads are now dumped, one by one, into a hopper at the side of the track. This hopper has an apron feeder in the bottom which delivers the coal to a short inclined conveyor; this in turn delivers to another and longer inclined conveyor running at right angles to the first conveyor line. These inclined conveyors are shown in the small bottom left-hand illustration in Fig. 1. The upper end of the short conveyor ends at a platform; the other and longer conveyor starting at this platform and running to a point above the feeder, discharging through a chute onto the same and thence onto the shaking screens again. This reprocessing installation is so arranged that the conveyors and feeder can be run at speeds to deliver between 50 and 500 tons of coal per hour. It is the practice of the company to keep these conveyors running at slow speed while the coal is being hoisted from the mine, so as to permit the conveyor coal to mix with the product from the mine on the shaking screens. Then in case of any temporary stoppage of hoisting, the conveyors are speeded up and the whole

FIG. 4. COAL-STORAGE PLANT AT ORIENT—TRESTLE AT LEFT AND RELOADING CRANE AT THE TOP

capacity of the screens can be delivered for a short time, thus equalizing the operation of the tipple.

The third feature is the overflow from the rescreener house. The rescreener house is shown at the right in Fig. 1; the overflow feature is depicted in the small illustration at the bottom and at the right of Fig. 1. The overflow is arranged as follows: A chute receives the screenings from the tipple as this coal is discharged from the long inclined belt conveyor at the top of the rescreener house. The chute delivers the screenings to an inclined conveyor (the lower part of this conveyor is shown in the small illustration in Fig. 1) which stocks the coal in a conical pile on the ground across the tracks from the rescreener house. This overflow chute can be placed in operation by simply opening a flap gate in the discharge from the conveyor at the top of the rescreener house, thus diverting the coal to the overflow apparatus. The coal can be recovered from the stock pile at any time, the locomotive crane loading it into side-dump cars; these cars may then dump the coal into the hopper of the reprocessing plant, which delivers it to the tipple shaking screens again.

Rescreener Overflow Proves Valuable in Operation

The special value of the rescreener overflow arises from the fact that the rescreener house pockets, or bins, occasionally get full and it is impossible to unload them without blocking the loading tracks. This overflow also enables the company to bypass the rescreener in case of car shortage; thus enough cars might be provided to take care of the main tipple whereby the lump, egg and nut would not be sent to the storage yard.

During these days it is customary to publish the names of "honor men" and firms connected with a worthy piece of work. In the case of the Orient plant, the original tipple structure was designed and built by the Wisconsin Bridge and Iron Co., of Milwaukee, Wis. The machinery in the original installation was furnished by the Scottdale Foundry and Machine Co., now the Marion Machine, Foundry and Supply Co., of Marion, Ind. The new installation in connection with the tipple was planned and the work was done in the field by the Allen & Garcia Co., of Chicago, Ill. The machinery was furnished by the Jeffrey Manufacturing Co., of Columbus, Ohio, the Stephens-Adamson Manufacturing Co., of Aurora, Ill., and the Skillin & Richards Manufacturing Co., of Chicago, Ill. The new rescreening plant was designed by the Allen & Garcia Co. and the steel work furnished and erected by the Wisconsin Bridge and Iron Co. The field work was done, aside from the steel erection, by the Allen & Garcia Company.

Among the other features of the plant is the Nordberg hoisting engine (made by the Nordberg Manufacturing Co., of Milwaukee, Wis.), which is the finest in the field. It is a 28 x 54-in. engine and was equipped last year with a cylindro-conical drum; the small diameter of the drum is 7 ft. and the large diameter 11 ft. This change in the drum has been the means of increasing the output of the shaft by at least 700 tons per day. Furthermore, the balancing of the hoist is so greatly improved by means of the conical drum that the engine is controlled and operated at a higher rate of speed than formerly, with much greater ease and safety and with a considerably greater steam economy. The latter feature is especially noticeable as the mine was often short of steam when hoisting with the old 10-ft. cylindrical drum. The hoisting cycle is such that more than three cars per minute can be handled constantly with a total hoist of about 600 ft. and a rope speed of about 4500 ft. per minute. The cylindro-conical drum installation was planned and executed by the Allen & Garcia Co. working in connection with the Nordberg Manufacturing Company.

In the same room with the hoisting engine is the electrical power plant, which includes a 350-kw. Nordberg-Corliss direct-current unit and a 500-kw. Fulton engine unit. The Fulton engine is made by the Fulton

Engine Works, Los Angeles, Cal. Power generated by these sets is used to operate the underground haulage, the mining machines and to run the surface machinery exclusive of the hoist. There is also a 65-kw. set furnishing current for lights. In the same building with the hoist and the generators is the steam power plant; it is of ample dimensions and capacity, and contains six 400-hp. Wickes vertical tube boilers, made by the Wickes Boiler Co., of Saginaw, Mich. The boilers are fired mechanically, being equipped with Green chain grate stokers, made by the Green Engineering Co., of East Chicago, Ind. The smallest sizes of coal are burned on these grates and it is conveyed to the boiler house hoppers, from which it is fed by gravity to the stokers.

The big brick stacks which are such a feature of the Franklin County field mark the location of plants as

FIG. 5. SAND-STORAGE AND DRYING PLANT AT ORIENT MINE

far as the eye can reach on all sides of Orient. The 175-ft. stack at this plant has an inside diameter of 8 ft. It is of Wiederholdt type (built by the Wiederholdt Construction Co., of St. Louis, Mo.) and is built of vitrified tile with honeycombed sections vertically. After the tile blocks are set, the sections are filled with concrete reinforced with rods which ties the whole construction solidly together.

There is a washhouse close to the main shaft with the usual equipment of lockers, hangers and sprays for 780 men. The washhouse was designed and built by the Allen & Garcia Company.

Water for the various needs of the town and plant comes from the Middle Fork of Big Muddy River. It is pumped by two centrifugals to a Booth water softener (made by the L. M. Booth Co., of Jersey City, N. J.) from which a boiler supply is sent to a 50,000-gal. tank as reserve storage.

This great preparation and coal-handling plant at Orient is noteworthy not alone for the excellence of the mechanical equipment but also for the comprehensive scheme for balancing the operation of the plant in the many emergencies which can be counted upon to arise during a year's or even a month's run. It also reflects the optimism as well as the foresight of the management. It has taken years to plan this operation, construct the plant and bring the underground development to the point where there is enough "coal in sight" (to borrow an expressive term from our metal-mining friends) to guarantee a steady and reliable flow of big tonnage from the mine face to the screens at the tipple. There was great depression in the coal trade in 1911 and again in 1914-1915—nevertheless this development was vigorously prosecuted and today, when coal is needed, the plant is able to turn out quantity shipments. Emergencies have been quickly met and new requirements speedily provided for as reflected in the improvements recently added.

The facts in this description of the Orient plant came from the authoritative sources of the management of the Chicago, Wilmington and Franklin Coal Co. and the Allen & Garcia Co., the engineering and constructing firm. *Coal Age* is appreciative of such courtesies.

Coal Prices in Ireland

Shortage of shipping, high freights, and the increased cost of labor have resulted in the price of coal being raised in Belfast, Ireland, until it is about double what it was before the war. Despite the shortage of tonnage, local dealers managed to maintain the imports to Belfast at the necessary standard, and they were able to supply all the demands made upon them. The total imports of coal into Belfast for 1917 amounted to 1,321,434 tons, which exceeds the figures for the last prewar year by about 8000 tons. The Government took over the control of coal prices and empowered the local authorities to appoint committees to fix the maximum charge per ton for each district. Subsequently it was resolved that the maximum price of household coal should be fixed at $10.95 per ton cash. Scheduled prices are being observed by making the charge of $11.19 per ton for the best English coal, subject to a discount of $0.243 for cash.

In exploration and recovery work at a mine following a disaster, the code of hoisting engines in general use should be followed. Copies of this code should be posted at the top of the shaft and be furnished the men who descend the shaft. If the regular signal devices have been destroyed, other methods of signaling must be improved. It is not safe to rely on any pipe running down the shaft, as it may be broken or entirely absent a short distance down. Hammers may be used for striking the bucket, or a triangle or short piece of T-rail may be suspended over the bucket or on the cage or float and be struck with a hammer. Two or more hammers should be taken, as one may be accidentally dropped into the shaft. Automobile horns may be heard in shallow shafts 200 ft. deep. A No. 8 wire may be used to advantage for signaling. The wire should be cut 10 ft. longer than the depth of the shaft, and the upper end should be attached to a counter-weighted bar of iron that will strike a suspended plate or circular saw when pulled.—*Rescue and Recovery Operations in Mines.*

Fans and Boilers

By W. D. OWENS
West Pittston, Penn.

SYNOPSIS — *The results of tests conducted upon mine fans were taken as a standard by which the capacities of similar fans used to furnish forced draft to boilers was determined. The amount of air thus calculated is then compared with the quantity required for complete combustion of the fuel used. The results showed some surprising air velocities and in one case resulted in the modification of the baffling.*

A SPECIAL test was made some time ago on two ventilation fans, and their efficiencies used as a guide to the probable efficiency of blast fans used in connection with boiler plants. This was done because of the difficulty in measuring correctly the quantity of air entering a blast fan, owing to the short air passage into this machine, and the whirling motion of the air entering the fan. While on this subject, I think it might be of considerable interest, since we know the tonnage of coal consumed at a boiler plant, to know also what quantity of air is necessary to be furnished each minute, so as to obtain the best results from the fuel consumed. We thus learn that there is a practical limit to the velocity of the gases traveling from the firebox into the stack.

The first ventilation fan tested was 20 ft. in diameter and 6 ft. 8 in. wide, with the blades bent forward in the direction of rotation of the fan. This machine running at 72 r.p.m. produced 113,850 cu.ft. of air per minute and developed a 1.2-in. water gage. The cubical contents in which this fan revolves at the above-stated speed $= 20^2 \times 0.7854 \times 6.66 \times 72 = 150{,}070$ cu.ft. (Small fractions in all the calculations in this article will be omitted, when possible, for the sake of simplicity). And the theoretical water gage for this speed will be $20 \times 3.1416 \times 72 = 4524$ ft., peripheral speed per minute, or

$$\frac{4524}{60} = 75.4 \textit{ ft. per sec.}$$

Therefore, assuming the average temperature to be about 60 deg. F. (which was approximately true when the test was made in the return airway), we have

$$\frac{75.4^2 \times 0.0765 \textit{ (the weight of air)}}{32.16 \times 5.2} = 2.60 \textit{ in. of water gage}$$

The percentage of mine water gage to the theoretical water gage equals $\frac{1.2}{2.60} = 46.15$ per cent. This shows that this fan cannot produce a large volume of air except when the air resistance is low.

Now, deducting the mine water gage from the theoretical water gage, we have 2.60 in. — 1.2 in. = 1.40 in. water gage. This pressure is consumed in the fan itself in forcing through it the 113,850 cu.ft. of air handled. Any fan should produce its own cubical contents when revolving in the open atmosphere and not connected in any shape or form with the mines or any other air duct; under such conditions the volume of air enters direct from the open atmosphere into the fan, and is thrown out by the blades in motion again into the atmosphere and the theoretical water gage is entirely consumed within the fan itself to force out this volume of air.

Assuming that all fans of this type or model are able to produce their own cubical contents per revolution, determine how much air a fan will produce under any given conditions above or below such standard. The cubical contents of this fan, as stated heretofore, is 150,070 cu.ft., and the theoretical water gage is 2.60 in. Therefore, when 1.2 in. of water gage of this 2.60 in. was taken to force the air through the mines, and up to the fan, we have a balance of 1.4 in. of water gage, which forced 113,850 cu.ft. of air through the fan itself. Since 2.60 in. of water gage should produce 150,070 cu.ft., what quantity of air should 1.40 in. of water gage produce? We now have the following proportion:

As $\sqrt{2.60}$: 150,070 : : $\sqrt{1.40}$: 110,153 cu.ft. But this fan actually produced 113,850 cu.ft. Therefore,

$$\frac{113{,}850 - 110{,}135}{150{,}070} = 2.47 \textit{ per cent.}$$

Hence, this fan is able to produce 2.47 per cent. above its own cubical contents per revolution when working against no head. The fan was built by the Vulcan Iron Works, Wilkes-Barre, Pennsylvania.

Second Fan Test

The second fan was a new one, built about two years ago by the Vulcan Iron Works, and, upon request, was furnished with straight or radial blades, bending neither forward nor backward. The fan was 24 ft. in diameter and 8 ft. wide, and ran at 72½ r.p.m. It produced 171,500 cu.ft. of air per minute, developing 2.40 in. mine water gage. The cubical contents of this fan at the above velocity equals $24^2 \times 0.7854 \times 8 \times 72.5 = 262{,}377$ cu.ft. and at this speed the wing tips traveled $24 \times 3.1416 \times 72.5 = 5466$ ft. per minute, or

$$\frac{5466}{60} = 91.1 \textit{ ft. per sec.}$$

Hence the water gage would be

$$\frac{91.1^2 \times 0.0765}{32.16 \times 5.2} = 3.79 \textit{ in.}$$

Now, 3.79 in. — 2.40 in. of mine water gage = 1.39 in. of fan water gage. This represents the pressure necessary to force 171,500 cu.ft. of air through the fan itself. Hence, the percentage of mine water gage to the theoretical water gage is as follows:

$$\frac{2.4}{3.79} = 63.32 \textit{ per cent.}$$

Therefore this is a better fan to develop pressure and volume than the preceding one. Now, what quantity of air should this fan produce, based on its cubical contents? We have as follows:

As $\sqrt{3.79}$: 262,377 : : $\sqrt{1.39}$: 158,840 cu.ft. Since the fan actually produced 171,500 cu.ft., we have 171,500

— 158,840 = 12,660 cu.ft., above its own cubical contents, or

$$\frac{12,660}{262,377} = 4.82 \textit{ per cent.}$$

It can be seen that this fan is a good one, and proves clearly the fallacy of having the blades of any fan bent either forward or backward as compared with the motion of rotation. It also proves that a fan can be depended upon to displace its own cubical contents, when the theoretical depression produced is entirely consumed within the fan itself. Therefore, the efficiency of a fan can be clearly calculated on the foregoing principles, if the purchaser will state the capacity of the machine when there is no resistance to be overcome. Of course, the temperature must be taken into consideration; but, under identical conditions the volume of air produced will be the same.

The gases resulting from the complete combustion of coal in air should not contain less than 16 per cent. of carbon dioxide gas. For, whenever the flue gas contains less than this amount, it is evident that too much air is allowed to pass through the furnace. Even on the basis of admitting one-third more air into the firebox than is theoretically necessary for complete combustion, the escaping gases should contain from 20 to 22 per cent. of carbon dioxide.

The molecule of carbon dioxide, or CO_2, is composed of one atom of carbon with an atomic weight of 12, and two atoms of oxygen with an atomic weight of 16. Hence, $\frac{2 \times 16}{12} = 2\frac{2}{3}$. Therefore, to convert 1 lb. of carbon into carbon dioxide requires $2\frac{2}{3}$ lb. of oxygen when complete combustion takes place. The composition of the atmosphere being made up of 23 per cent. of oxygen, by weight, and 77 per cent. of nitrogen, by weight, it is clear, since we need $2\frac{2}{3}$ lb. of oxygen from the atmosphere, that we must accept 8.94 lb. of nitrogen with it; for, as $23 : 2\frac{2}{3} :: 77 : 8.94$ Hence, to complete the combustion of 1 lb. of carbon we must consume 11.61 lb. of air ($2\frac{2}{3} + 8.94 = 11.61$). Now, since 1 cu.ft. of air weighs 0.0765 lb. at a temperature of 60 deg. F. (which is a fair average), we have to furnish $11.61 \div 0.0765 = 152$ cu.ft. of air for every pound of carbon consumed.

Best Practice Calls for More Air

This, of course, is the theoretical quantity necessary, but the best boiler-room practice calls for from one-third to one-half more air in addition. We will assume that an addition of one-half is admitted. Thus $152 + 76 = 228$. Therefore, for every pound of coal burned (assuming that every pound of coal contains 100 per cent. carbon) it requires about 228 cu.ft. of air to pass through the firebox.

In all probability the coal consumed under the boiler does not contain more than about 80 per cent. of carbon, but when we take into consideration the quantity of oxygen and hydrogen it also contains, which averages about 7½ per cent. according to the geologists, Rodger and Johnson, every pound of coal consumed under ordinary boilers will be fully equivalent in heating capacity to a fuel containing about 90 per cent. carbon. Hence, $228 \times 0.90 = 205$ cu.ft., and this for convenience can be reduced to 200 cu.ft. of air that must be furnished for every pound of coal consumed in order to secure sufficient oxygen for complete combustion to CO_2. This combustion should develop $14,550 \times 0.90 = 13,095$, or say 13,000 B.t.u. of heat for every pound of coal thus consumed. But, if any of this combustible escapes in the form of CO, it must be remembered that not to exceed 4200 B.t.u. will be developed.

We will now consider the two separate boiler plants at Heidelberg No. 1 and Exeter collieries, and ascertain what quantity of air is necessary to be furnished to the boilers at each.

Coal Consumption at Heidelberg Colliery

The Heidelberg No. 1 colliery power plant comprises four return-tubular boilers of 150 nominal horsepower each, and one battery of Stirling boilers of 300 hp., or a total of 900 hp. The coal consumed at this particular colliery averages about 1200 tons per month of 30 days, full time, or about 2,688,000 lb. This is equivalent to about 62½ lb. per minute; and since no steam is necessary for 12 hours of each day, and 24 hours on Sundays, except for pumping and ventilation, it is evident that about one quarter more coal than the average amount must be furnished during the 12 hours on the operating days. Hence, we have $62\frac{1}{2} + 15.56 = 77.81$ lb. consumed every minute during the operating period. For convenience' sake, we shall call it here 75 lb. per minute. Hence, this plant must be furnished with $75 \times 200 = 15,000$ cu.ft. of air per minute.

As stated heretofore, this plant is composed of four return-tubular boilers each 6 x 18 ft. These each contain 76 four-inch diameter flues, through which the gases return to the stack. Now, since 15,000 cu.ft. of air is necessary per minute, each boiler-horsepower will require $15,000 \div 900 = 16.66$ cu.ft. of air per minute. Consequently, one return-tubular boiler requires $16.66 \times 150 = 2500$ cu.ft. of air per minute. This boiler contains 76 flues each with an internal diameter of 3.73 in. and, therefore, the cross-sectional flue area is equal to 5.76 sq.ft. Hence the velocity of the gases going through these flues, when the boiler is thus forced, equals $2500 \div 5.76 = 434$ lin.ft., nearly, per minute (omitting the amount of carbon combined, which in this case is about 1/18 more). But since the average temperature of the return gases passing through the tubes cannot be less than about 1000 deg. F., this volume increases proportionately. Thus, as $0.0284 : 2500 :: 0.0765 : 6734$ cu.ft., and this latter figure divided by the area of the flues gives

$$\frac{6734}{5.76} = 1170 \textit{ lin.ft. (nearly)}$$

velocity per minute, or about 19.5 lin.ft. velocity per second.

When the boilers are thus forced the resistance becomes so great, owing to the small area compared with the rubbing surface of the tubes, combined with the above-stated high velocity, that the vacuum created at the foot of the stack, arising from the difference in temperature between the escaping gases going through the stack and that of the outside atmosphere, is not sufficient to force out the necessary quantity. The result is that part of the air forced through the fire by the blast fan must blow out directly through the firedoors into the boiler-room proper, and into the face

of the fireman. This also prevents any fresh air from entering the firebox from the boiler room, which is highly desirable when fresh coal is fired because generally some of the gases leaving the fire escape in the form of CO, or carbon monoxide. A small quantity of fresh air entering the combustion chamber at such times reconverts the CO into CO_2. It is important to secure this result since complete combustion into CO_2 produces 14,500 B.t.u. of heat, while the combustion to CO develops only 4200 B.t.u. per pound of carbon consumed.

In order to furnish the aforementioned quantity of air and force it through the grates and other gas passages, the blast fan has to run at from 130 to 150 r.p.m. The diameter of the fan is 8 ft. and its width 3 ft. 2½ in. In one of the tests made the fan was running 130 r.p.m., producing a water gage of 0.6 in. The cubical contents of the space occupied by this fan is 160.8 cu.ft., and this times 130 = 20,900 cu.ft. The theoretical water gage for this speed is 1.338 in. Deducting from this the 0.6 in. actually produced leaves 0.738 in., as the water gage consumed in the fan itself. Therefore, to find the quantity of air this fan produces under the conditions of the mine fan test, we have the proportion $\sqrt{1.338} : 20900 :: \sqrt{0.738} : 15{,}500$ cu.ft. It was calculated, heretofore, that 15,000 cu.ft. of air was necessary to proper combustion at this plant, and taking into consideration the waste, this fan must be producing a little more than its cubical contents.

The Exeter colliery steam plant has two batteries of Babcock boilers of 300 hp. each, and three batteries of Stirling boilers of 463 hp. each, making a total of 1989 hp. The consumption of coal at this colliery averages about 4000 tons per month of 30 days, full time, or about 210 lb. of coal per minute. During the days when the mines are in operation this colliery again has to burn about one-eighth more coal than the average consumption. Therefore, we must add 26 lb. per minute, making a total of 236 lb., or say 230 lb., so as to be on the safe side of the ledger. Now, since we must use 200 cu.ft. of air per pound of coal, we have 230 × 200 = 46,000 cu.ft. of air that must be furnished through the fireboxes every minute. The horsepower of this plant, as previously stated, is equal to 1989. Hence $\frac{46{,}000}{1989} = 23.12$ cu.ft. of air (nearly) per horsepower per minute.

One battery of Stirling boilers is equal to 463 hp., and 463 × 23.12 = 10,700 cu.ft., necessary for one battery. The passage into the stack, as originally constructed, was 1 ft. 5 in. by 15 ft., equals 21.25 sq.ft. Across this extends 30 water tubes, each 3.25 in. in outside diameter, thus cutting the effective area down to 9.75 sq.ft., through which the gases must pass in order to escape. The temperature of the gases at this point cannot be less than about 600 deg. F., or their weight will be about 0.0376 lb. per cu.ft. Since 10,700 cu.ft. is necessary at a temperature of 60 deg. F., or a weight of 0.0765 lb. per cu.ft., we have the proportion 0.0376 : 10,700 :: 0.0765 : 21,770 cu.ft. Consequently, $\frac{21{,}770}{9.75} = 2230$ lin.ft. velocity per minute.

It was shown, when discussing the Heidelberg return-tubular boilers, that the lineal velocity leaving the boilers was about 1170 ft. per minute; therefore, the velocity of the gases leaving the Stirling boilers at this colliery was unreasonable before the escape opening was enlarged. There is no wonder that the flames from the fireboxes were blowing out into the fireroom and into the face of the fireman.

The stacks are 5 ft. in diameter, or 19.635 sq.ft. in cross-sectional area. The area of the stack is the same in proportion as are the stacks used on the return-tubular boilers. These are 34 in. in diameter, or 6.30 sq.ft. in cross-section for a boiler of 150 nominal horsepower. Therefore, 150 : 6.30 sq.ft. :: 463 : 19.44 sq.ft., practically the same as the area of the 5-ft. diameter stack. There are dampers attached to these stacks, but they cannot be operated because the volume of the gases passing through the flue and stack is equal to the power of the vacuum developed between the temperature of the two atmospheres inside and outside. The stacks, even now, after the change in area, should be about 10 ft. higher.

The fan at this plant, when the test was made, was running 90 r.p.m. This machine is 14 ft. in diameter, 5 ft. 6 in. wide at the center and 4 ft. 9 in. at the tips of the blades. This gives a cubical content in which the fan is revolving of 800 cu.ft.; hence 90 × 800 = 72,000 cu.ft. of air. The machine developed 1.1 in. of water gage when the test was made. The theoretical depression at this velocity is 2 in. (nearly); therefore, the quantity of air this fan should produce is shown by the following proportion:

$$\sqrt{2} : 72{,}000 :: \sqrt{0.9} : 47{,}000 \ cu.ft.$$

It was heretofore shown that this plant required 46,000 cu.ft. per minute, and considering the amount of waste that takes place in the ashpits the quantities agree closely.

It has been shown that the average velocity of the gases going through the flues of the return-tubular boiler was about 1170 ft. per minute, and that at such a rate the flames in the firebox blew out through the doors. This proves that the velocity should not be higher than about 800 ft. per minute whenever the ratio of the rubbing surface to the area of the passage is as 1 to 230. That is, the area of one flue in the 150-hp. return-tubular boiler is $3.73^2 \times 0.7854 = 10.927$ sq.in., and this multiplied by 76 = 830.45 sq.in., or 5.76 sq.ft. But the rubbing surface of these flues each being 3.73 in. in internal diameter and 18 ft. long, or 216 in., equals

$$\frac{3.1416 \times 3.73 \times 216 \times 76}{144} = 1335 \ sq.ft.$$

And this divided by the area, equals

$$\frac{1335}{5.76} = 231$$

Therefore, the ratio is about 1 to 230.

The ratio of the rubbing surface to the area of passage in the Stirling or Maxim boilers is materially less than in the return-tubular type. Nevertheless, it is plain that the velocity of the gases leaving the boiler proper and entering the stack should not be higher than 1500 lin.ft. per minute.

Looking down into the flue passage of a Stirling 463-hp. battery, the flue area equals about 15 ft. by 3 ft. 2 in., or 47.5 sq.ft.; but this passage contains

120 water tubes each 3¼ in. in diameter, which occupy a space of about 6.91 sq.ft. Hence there remains about 47.5 — 6.91 = 40.59 sq.ft., or say 40 sq.ft., as the true average free area. The rubbing surface is of about 36-ft. perimeter and an average length of 10 ft., or 360 sq.ft. This times three, since there are three batteries, makes 1080 sq.ft. The surface of each water tube equals

$$\frac{3.1416 \times 325 \times 120}{144} = 8.5 \; sq.\,ft.$$

This times 120 tubes equals 1050 sq.ft., and this multiplied by three makes 3150 sq.ft. of rubbing surface in the water tubes. Hence, we have 3150 + 1080 = 4230 sq.ft. of total rubbing surface.

It was shown heretofore that when 2500 cu.ft. of air was forced through the grates of a return-tubular boiler, that the flames would blow out through the firedoors quite forcibly; and that if the whole amount of this air was to go through the flues the velocity would reach about 1170 ft. per minute. This would indicate that the velocity should not exceed about 800 ft. per minute; or say 2200 cu.ft. per minute as the greatest quantity that should be furnished to a return-tubular boiler of this size. Hence, the quantity that should go through the passages of a 463-hp. Stirling boiler will be directly as the ratios of the areas and inversely as the square roots of the rubbing surfaces. These proportions are as follows:

Direct .....5.76 : 2200 :: 40 : 15270 cu.ft.

Inverse.....$\sqrt{4230}$: 15270 :: $\sqrt{1335}$: 8600 cu.ft.

Since writing the foregoing, I find that the average length of the water tubes in the Stirling boilers is about 12 ft., and the quantity of air would thus be proportionately less, owing to the greater resistance, so that instead of 8600 cu.ft., it could not be more than about 7000 cu.ft., while it was stated previously that 10,700 cu.ft. was necessary. It is evident, therefore, that either the area of the passage had to be made much larger, or the boiler stacks would have to be made much higher, which of course would accomplish the same result.

Now, however, since the dimensions of the first and second baffle openings have been enlarged, and 7 in. added at the outlet into the stack, no flames are blowing out through the firedoors when the boilers are forced and the steam pressure can be kept higher and more constant.

Minecdotes

Getting a Bit of Their Own Back

In the earlier days of the war, before the seriousness of the outcome was recognized as it is at the present time, the shortage of coal and the scarcity of labor with which to mine it was hailed with outspoken pleasure by the employees of a certain small mine who had hitherto shown no great discontent with their lot.

"They," meaning the capitalists, of course, "have been putting it all over us every which way for years, and right here is where we get a bit of our own back," was the sentiment generally expressed; while a few of the more knowing ones insisted that "some of those fellows must be getting kind of hard up for easy money, else there'd have been no war; and it's up to us to get our share while we've the chance."

This simply meant that instead of loading only clean coal, for which they were paid good wages, rock, bone, slate and anything black enough which came along were all loaded in together. Naturally, the reputation of the mine began to suffer, and the management were at their wits' end to know how to cope with the situation, since dismissal as a means of discipline was useless in the face of the difficulty they had to replace the men who left.

Finally, a bright idea occurred to the pit boss, who began to keep a sharp lookout on the cars, ordering the dirtiest to be dumped in a place conveniently handy for loading when required. A hard cold snap coming on about that time, it wasn't long before quite a rush of orders came in from the company's own men, and these were filled from this dump.

The grouching and grumbling and general all-round fussing that went on when the trick was discovered was met with bland astonishment by the management, who innocently inquired: "What did they want, anyhow? They were getting the same coal they had mined themselves, weren't they? If the stuff wasn't good enough to suit them, how did they expect other people to put up with it?"

A few weeks of domestic discomfort, short tempers, poorly cooked food and belated meals helped a little more to convince the men that "easy money" could be too dearly bought, and it wasn't long before most of them came round to a saner view of the matter when this side of the "getting-a-bit of-their-own-back" question had been demonstrated.

Pride and Percy Verance

In one mine in West Virginia the miners are Welsh, Italian and Australian. Considerable rivalry exists between the several nationalities, but the Welsh hold the lead, beyond question. They are great coal miners; it seems to be born in the blood.

At the mine in question most of the work is contract, very little "company" work being done. One day the pit boss in making his rounds came upon two Welsh miners working at the face. It seems they were having a hard time, but were determined not to lay down. The pit boss asked how things were going.

"How goes it today, boys?"

"Pretty hard, boss; she sure is tough."

"Well, boys, perk up; all you need is pride and perseverance to keep you, and it will come all right." As he was walking back down the entry he heard the two miners stop working. He stopped and listened to the conversation.

"Say, Di, who is them fellows the boss was a-talking about?"

"I don't know. Who was he a-talking about?"

"That Pride and Percy Verance."

"Oh them! They must be the two wops on the night shift."

Research and Progress in Byproduct Coking in Great Britain—III

By J. B. C. KERSHAW
Colwyn Bay, Liverpool, England

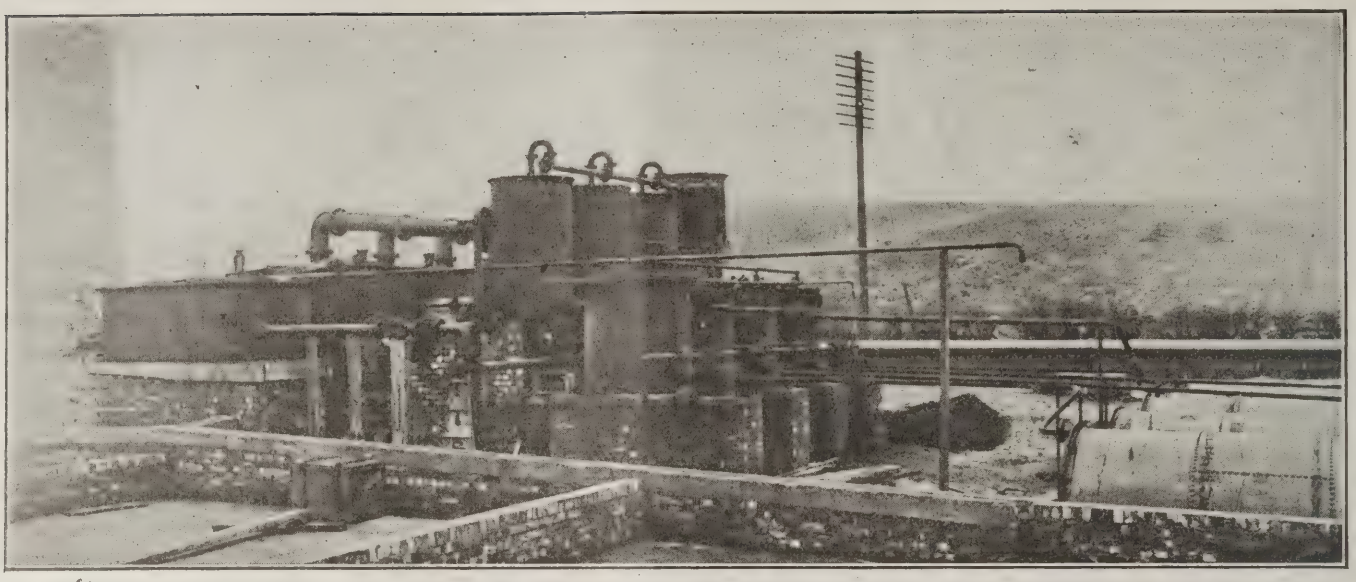
SYNOPSIS — *The refinement of benzol and the extraction of benzene, toluene and xylene, the three most valuable constituents, is an interesting process. Much care and careful control of temperatures must be exercised in this process in order to secure the best results.*

BENZOL is a term which, in byproduct coking practice, is used to cover a mixture of compounds of which benzene, toluene and xylene are the more valuable and important members, while certain sulphur compounds—paraffins, phenols, pyridine and naphthalene—are present as impurities. The recovery and rectification of benzol, therefore, is directed to recovering and obtaining in the pure state as large a quantity as possible of the three first-named carbon "ring" compounds from the coke-oven tar and gases.

It may not be out of place to note here that the benzol produced by the modern coke oven is derived from two sources—the tar and the gas. Prior to 1914, the larger portion of the benzol recovered came from the light-oil fraction of the tar distillate, but now the gas furnishes the greater amount.

As evidence of the rapid extension of the benzol recovery plants in the United States, the following figures from a report by C. E. Lescher, of the United States Geological Survey, may be quoted: In 1915 the output of benzol and other light oils by all the byproduct coking plants in the country was estimated to be 13,942,763 gal., and only about one-half of this total was refined in the works where it was produced. From eight to nine million tons of coal were carbonized in the coke ovens that produced this light oil, and the 6,620,096 gal. refined at the byproduct coke works produced 4,833,939 gal. benzol, 1,315,727 gal. toluol and 470,425 gal. solvent naphtha.

Twelve months later the capacity of the benzol-recovery plants in operation in the United States was estimated to be 20,000,000 gal. per annum; while at the present time it is considerably over this amount—probably approaching 30,000,000 gallons.



The corresponding figures for the United Kingdom are not available for publication; but according to Walmsley, at the beginning of the war practically the whole of the benzol produced in this country was obtained from byproduct coke ovens. The supply from this source amounted to 32,000,000 gal. per annum. The coal carbonized in English gas works would, however, yield another 60,000,000 gal. of benzol, and since all the leading gas works in the United Kingdom are now washing their gas with creosote oils and extracting the benzol, it follows that the English production of this carbon compound is now largely in excess of the 38,000,000 gal. estimated as the output in 1914.

In the following pages a résumé will be given of recent papers and articles which have appeared in English technical publications on benzol recovery and rectification.

The extraction of benzol from the waste gases of coke ovens is carried out in all plants on the same prin-

GENERAL VIEW OF HIRD CONTINUOUS TAR DISTILLATION PLANT

ANOTHER VIEW OF A HIRD CONTINUOUS DISTILLATION PLANT

ciple and by similar means. The tar and ammonia are first removed from the hot gases by cooling, spraying and treatment with sulphuric acid. Then, after further cooling, preferably down to atmospheric temperature, the gases are washed with creosote oil, in order to absorb the benzene, toluene and xylene which have escaped absorption by the tar. If the cooling of the gases be carried too far before the tar is separated, or if the gases are left too long in contact with the tar, the latter will contain a larger proportion of benzols and of the light oils when distilled; but in no case can complete separation be effected in this way, and therefore the use of creosote oil for washing the gases is always required. The oil, after the absorption of the benzol from the gases, is subjected to distillation by means of direct heat, or by steam, and the product obtained by condensing the distillate is the crude 65 per cent. benzol of commerce.

Recent progress and research in the United Kingdom have been devoted toward improvements in carrying out the foregoing process, and no very fundamental changes in principle or method have been made, or are to be expected. The best results no doubt can be obtained when the wash oil is atomized or sprayed into the gases, since this method produces a more intimate contact of the absorbing medium with the products to be recovered. The cooling of the wash oil is easily carried out in this case, by placing the suction and pressure pipes connected to the circulating pump in a cold water or brine solution.

As regards the chemical and physical characteristics of the creosote oil used for absorption, it is important that this should be as free as possible from naphthalene, and quite free from water. Walmsley and Morley in a paper read before the Manchester District Institute of Gas Engineers in November, 1916, give the following specification for a suitable oil:

RETORT TEST WITH BULB OF THERMOMETER IMMERSED IN LIQUID

Specific gravity	1.035
Dropping point	210 to 220 deg. C.
50 per cent. distils over at	250 deg. C.
80 per cent. distils over at	300 deg. C.
Water content	Traces

On cooling the distillate (obtained up to 300 deg. C.) to 7.2 deg. C., and maintaining this temperature for 30 minutes, the solid naphthalene settling out, on being filtered and pressed, should not amount to more than 7 per cent.

With regard to the presence of water, the authors of this paper point out that care is required at four points if the washing oil is to be kept free from this objectionable constituent.

The presence of water in the oil may be due to: (1) Water carried over in mechanical suspension in the gas from the scrubbing apparatus immediately preceding the oil-washing apparatus. (2) Water deposited in the oil, due to the temperature of the gas being reduced in the oil scrubber. From this it follows that the incoming oil should be at a slightly higher temperature than the gas. (3) In steam-heated stills water may be condensed in the oil by defective working of the still due to (a) the supply of steam being in an insufficiently dry state, (b) condensation of steam in the still due to low temperature of entering oil. (4) Lastly, there is the water which may be present in the oil when purchased.

The efficiency of a benzol washing or "scrubbing" plant, however, depends upon many other factors besides the quality and amount of the wash oil, and J. A. Wilson, in a paper read before the Coke-Oven Managers' Association at Sheffield, in November, 1916, stated that one of the chief of these was that of laboratory control, which should include daily tests of the gas, before and after it had passed the scrubbers, and regular sampling and testing of the oil at various points in the circulating system. The temperature of the gas and the area of the scrubbers or absorbing chambers, in relation to the volume of gas to be dealt with, are also factors of importance, and Mr. Wilson in his paper stated that at the Devonshire coke works at Staveley they used "the ordinary scrubbers filled with boards, the final scrubbing, however, taking place in rotary scrubbers. The distribution of the oil in the tower scrubbers is effected by means of ¾-in. pipes, radiating from a 3-in. circular cast-iron main. . . . The area of the scrubbers should be such that ample time contact is allowed between the gas and oil, more particularly as the process of benzol absorption by creosote oil is a purely mechanical one. A good allowance for the space to be occupied by the scrubbing boards is 16 cu.ft. per ton of coal carbonized per day. The amount of oil circulated should be such that a saturation of not more than 3 to 4.5 per cent. is shown, the water content of the oil being approximately 1 per cent."

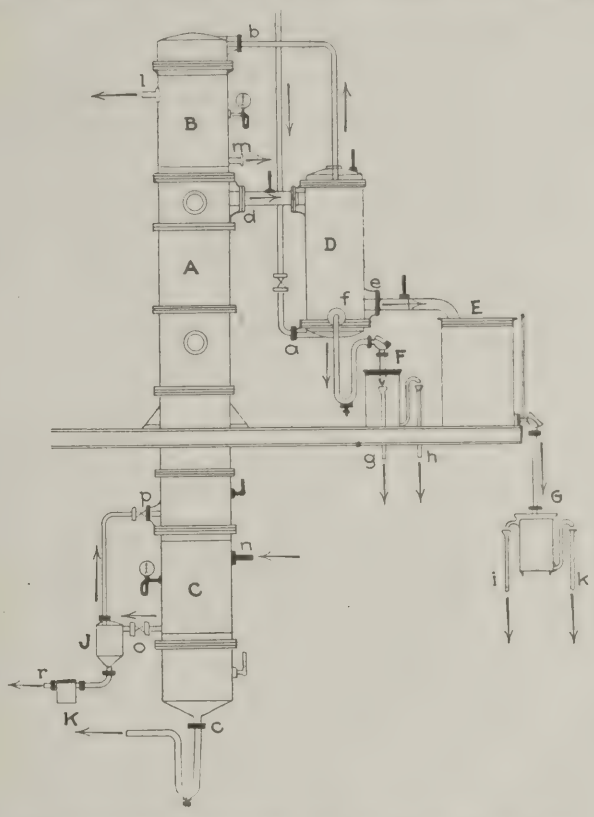
With reference to the effects of the temperature of the gases and of the presence of water upon the absorptive power of creosote oil, W. Diamond, manager of the Marley Hill Coke Works, County Durham, has contributed some figures bearing on the subject to the *Gas World* of Mar. 2, 1918. These are reproduced, together with his remarks, below:

To recover the maximum quantity of benzol from coal gas the washing oil should have a specific gravity between 1.04 and 1.06. Coal-tar creosote absorbs five times as much benzol as filtered anthracene oil. The amount of water in the washing oil should not exceed 1 per cent.; the presence of 2.5 per cent. in creosote oil reduces its efficiency by over 35 per cent.; 7.5 per cent. by 45 per cent. and 10 per cent. by 73 per cent. By reducing the temperature of the gas below 15 deg. C. and that of the washing to 0 deg. C., absorption is increased by 20 per cent., but the cost is prohibitive. The extraction of 2.1 gal. of benzol from gas per ton of coal results in a decrease of 4.5 per cent. in the calorific value of the gas, removal of 2.5 gal. produces a decrease of 7 per cent., and of 3 gal. a decrease of 8 per cent.

ABSORPTION OF BENZOL

	Gal.
Coal-tar creosote free from water	0.22
Coal-tar creosote 2.5 per cent. water	0.14
Coal-tar creosote 5.0 per cent. water	0.14
Coal-tar creosote 7.5 per cent. water	0.12
Coal-tar creosote 10 per cent. water	0.06

When the quantity of water becomes 10 per cent. and over, the results are irregular; but below this the results seem regular. It is of course necessary that the lowest possible temperature to which one is able to reduce the gas should be used, as the lower the temperature of the wash oil and gas the greater the affinity.



There are two methods of recovering the benzol from the creosote oil used for absorbing purposes—by heating in direct-fired stills, using either solid or liquid fuel, and by heating in steam-heated stills or columns. For small plants the former method is the simpler and the apparatus therefore is the less costly to erect. But when the works is dealing with the gas produced by coking 50 tons of coal per day or over, the steam-heated still is usually employed, since it is much the more easily controlled and in fact is almost automatic in its action. In a recent paper on this subject, read at Sheffield before the Midland Section of the Coke-Oven Managers' Association by J. B. Hamer, manager of the coking plant of the Middleton Estate and Colliery Co., of Leeds, the author stated as follows:

The modern type of plant for treating saturated oils after they have absorbed the benzol products from coal gas is the continuous steam-heated still. This plant has gradually reached a high standard of perfection by the addition of improvements which have aimed at economy in the fuel consumption, high stripping efficiency and good quality of the crude benzol. The arrangements consist of stills, preheaters, heat exchangers, superheaters, dephlegmating devices, condensers and oil coolers. The aims of the designers of the various plants have been to heat the wash oil to as high a temperature as the available steam heat will permit, and to do so as economically as possible. Thus there are the superheaters giving the final temperature to the oil entering the still, and preheaters and heat exchangers as aids to economy. The consumption of steam in the recovery of one ton of 65 per cent. benzol amounts to from 3 to 4½ tons, the production thus costing from $1.25 to $1.87 per ton in fuel alone.

The main advantages of the continuous steam stills as against the direct-fired pot stills of earlier days are less danger from fire, smaller plant (hence smaller capital charges) and the smaller oil storage necessary. The disadvantages are that efficiency is dependent on an absolutely uniform steam temperature, and that there are more complications—more moving parts—and higher fuel consumption.

No doubt in many of the continuous steam plants much waste of steam ensues owing to faulty design of the still proper. Simon-Carves & Brown have lately introduced an improvement in this direction. This consists of an internally arranged preheater in the still, so that the wash oil as it gravitates through the apparatus gains heat during debenzolization, thus doing away with the anomaly of the older type of plant, where the wash oil loses heat in the still. With regard to stills in which the wash oil loses heat in its passage, this type is not only wasteful and irrational but some of us are aware from costly experience of the difficulties which occur when part of the elaborate preheating or heat-exchanging plant fails. The anomaly referred to then becomes an accessory to conditions which lead to chronic emulsification of condensed water and oil.

Discussing the practical details of the working of a crude benzol plant, the author makes some sensible

KUBIERSCHKY SYSTEM OF TAR DISTILLATION

remarks upon the differences of opinion which exist among managers upon such questions as: (a) The best temperature for the wash oil to enter the still. (b) The temperature of the stripped oil leaving the still. (c) What should the "light-oil" content of the debenzolized absorbent be? (d) How does the percentage of water remaining in the oil affect its absorbent efficiency in the gas washers? (e) What is the best strength to make crude benzol? The author explains that the variety of opinions expressed in respect to these questions is due to the fact that there are no two plants exactly similar in every detail, and that each manager naturally is in favor of the conditions which have been found to give the best results in his own plant.

Concerning the important questions of still design and steam consumption, Mr. Hamer gave the following useful notes and hints:

With the still which makes no provision for the addition of heat during debenzolization the wash oil should leave the indirect steam-heating system within 10 deg. C. of the steam temperature; otherwise the preheating and superheating system is inefficient, and excessive consumption of direct steam may be expected in the still.

The outlet temperature of the oil, when it is less than the inlet temperature, is seldom very much of a guide to the working of the plant. Provided that the wash oil is sufficiently hot when it enters the still, the quality of the crude benzol is regulated by the direct steam admitted and by the dephlegmating devices. These latter should have sufficient latitude to be independent of the heat-exchanging system, and ample provision should be made for preventing the dephlegmating light oil, naphthalene and water of condensation passing back again through the still. The higher the temperature of the oil leaving the still the less chance is there of water passing away with the oil, and thus of a reduction in the efficiency of the oil-cooling plant. Owing to the use of about one ton of direct steam on the production of one ton of crude benzol, the outlet temperature of the oil will generally be found between the limits of 102 and 108 deg. C. The factors affecting this particular temperature are the saturation of the wash oil, the height of the still, the speed of the oil passing through the system and the temperature and quantity of the direct steam necessary for the quality of crude benzol produced, so that in reality there can be little control of this temperature.

The quantity of direct steam admitted to the still should, in conjunction with efficient preheating, be sufficient to insure the removal of all the products absorbed by the oil at the scrubbers, so that the efficiency to be aimed at is to have the debenzolized oil of the same quality as the fresh unused absorbing oil—that is, giving not more than

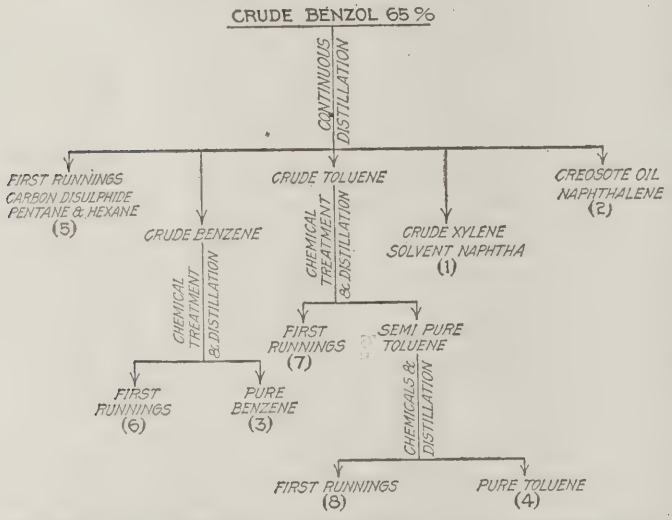


DIAGRAM ILLUSTRATING PURIFICATION OF BENZOL BY CHEMICAL TREATMENT AND DISTILLATION

The distillates numbered 1, 2, 3 and 4 are final products; 5, 6, 7 and 8 are distillates returned to the process for further treatment. Product 4 (pure toluene) is the most difficult to prepare, and sometimes four distillations are required, with chemical treatment between each, to obtain it in the pure state.

5 per cent. distillate at 200 deg. C. It then requires very efficient fractionation of the distillate leaving the still to insure that the crude benzol does not leave more than 10 per cent. of residue when distilled in a retort to 190 deg. C. The dephlegmates from the vapors distilling require careful separation of the condensed water, and cooling, in order to remove as much naphthalene as possible. The clear oil is then usually returned to the absorbing oil, but where a tar-distillation plant is available more profitable uses may be found for it.

Other problems of benzol rectification discussed in this paper were the effects of water on the absorbing oil, the importance of systematic tests, washing the "once-run" products and the final rectification.

The most efficient of the modern types of continuous steam-heated debenzolizing stills is probably that of Gasser, the design of which recognizes the fact that a washing oil saturated with benzol requires less heat to liberate the benzol than one which is not so highly charged. The temperature in the Gasser still, therefore, increases as the oil loses its benzol contents. The principle of countercurrent heating is adopted to obtain this result, the oil entering the still with a temperature of 110 to 115 deg. C. and leaving it with a temperature of 130 to 145 deg. C. The total steam consumption in the Gasser still is stated by Hamer to be about 2¼ tons per ton of 65 per cent. benzol produced.

As this type of still may be new to some of the readers of *Coal Age*, the following description of it, abstracted from an article in the *Révue Générale Chimie* by L. Fabre (through the *Chemical Trade Journal*, of Nov. 3, 1917) is here given.

The saturated oil enters first into a tubular heat exchanger and is heated by the benzol vapors and steam coming from the stills. The oil then passes into a second heater, which acts at the same time as a hydraulic seal or closure for the still, and in which the heat exchange is effected by the hot benzol-free oil coming from the stills. The oil then passes into a third reheater, consisting of cylindrical elements provided with superheated steam coils, and passes thence into the distilling apparatus. This consists of a number of cylindrical elements furnished with steam coils and jets. The coils maintain the necessary temperature and the jets remove the benzol. After leaving the stills, the oil passes through the reheater above described, and after cooling it is conveyed to the column. On the other hand, the mixture of steam and about 50 per cent. benzol are conveyed from the still into a dephlegmator, the surface of which consists of cylindrical cells, thence into a second dephlegmator consisting of three tubes filled with coke, to absorb the last traces of oil. The mixture goes thence into the oil reheater and finally into a cooler, where it is cooled down to 20 deg. to 25 deg. C. The water and benzol are then separated in the usual way.

An improved debenzolizing process and apparatus which requires no steam at all is, however, the latest advance in benzol recovery. Such a process was described in a paper read by W. Greaves before the Midland Section of the Coke Oven Managers' Association, at Leeds, in February, 1918.

An apparatus based on the same principle was tried 15 years ago for separating the first fractions of the distillate in tar distillation. It has been applied lately with success to the recovery of benzol from the wash oil.

The benzol is extracted from the gas by the usual method of scrubbing, but instead of the benzolized oil being then brought into contact with live high-pressure steam in the ordinary form of benzol still, it is pumped under pressure through a cast-iron coil heated to a temperature of 145 deg. C. by hot furnace gases. The hot benzolized oil is sprayed into a small still, or dephlegmator, the inside of which is at atmospheric pressure. The benzols and water vapor pass away to a condenser and separator to divide the condensed water from the benzol, while the dehydrated and debenzolized oil flows to the oil coolers, to be again used for absorbing the benzol from the gas. In this simple manner it is easy to produce the ordinary 65 per cent. crude benzol. The advantages of the method are as follows:

1. Small capital cost. The plant requires no house; ground space covered is small; the parts of the apparatus are less expensive than that required for the ordinary method of producing crude benzol.

2. Any inferior fuel can be used for heating the coil. It enables the heat in the fuel to be employed direct.

3. Simplicity of working. All that the attendant has to pay attention to are the fire, pump and thermometer.

4. Durability. The installation to which reference is made was started some 20 months ago and was stopped only a few days ago, as it was thought desirable to test the duplicate set of coils. The latter are working with equally satisfactory results.

5. Quickness of erection. The plant was set to work within four months.

This system of treating the oil and separating the benzol is of course much cheaper and simpler to operate than any of the steam-heated continuous stills, and Greaves estimates the fuel cost per ton of recovered benzol to be under 50c. per ton.

Crude Benzol and Its Rectification

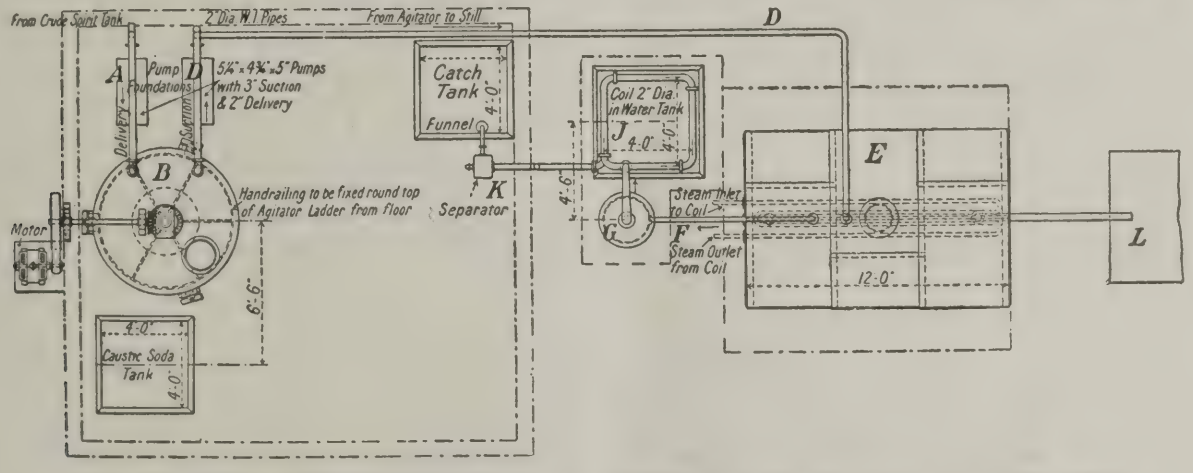
The crude benzol obtained by debenzolizing the wash oil is a mixture of benzene (C_6H_6), toluene (C_6H_5—CH_3) and xylene (C_6H_4—$2CH_3$), with certain impurities. It is classed and known as 30, 50 or 90 per cent. benzol, according to the amount which distils over before the thermometer in the distillation test flask touches 100 deg. C. The boiling point of pure benzene is 30.5 deg. C., of pure toluene 111 deg. C., and of pure xylene 139 deg. C., so that the separation by repeated fractional distillation of these three constituents of commercial benzol from the impurities and from each other is quite possible. The hydrocarbons which distil after the xylene are known as solvent naphtha. This contains "cumene" in addition to other more complex compounds.

The relative proportion of the various constituents contained in crude benzol of course varies with its source and the conditions of its recovery, but the following may be taken as an average yield for English practice:

	Per Cent.
Benzene (90 per cent.)	60 to 65
Toluene (90 per cent.)	5 to 8
Solvent naphtha	6 to 8
Heavy naphtha	4 to 6
Total	75 to 87
Losses in washing and in absorbing oil	10 to 20

Modern rectification practice in the byproduct coke works in England is based on redistillation, chemical treatment and fractionation. The redistillation has for its purpose the separation of the naphthalene and those fractions of the absorbing oil which have been carried over with the steam in the debenzolizing process. It is carried out in large stills and is called "blowing-over." Either two or three fractions are collected, according to the scheme of after treatment in view.

In works where it is not intended to carry the refining process further, the usual plan is to obtain two fractions—the light oils which come over up to the appearance of steam and the heavy oils, which follow until naphthalene makes its appearance at the condenser exit.

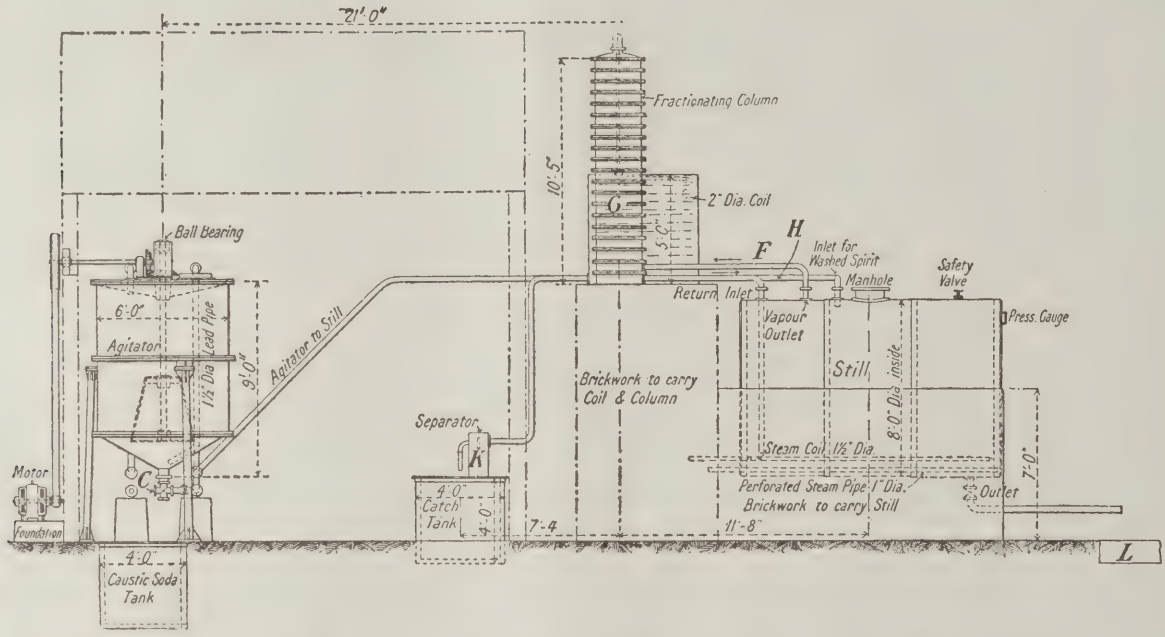


In those works, however, where the production of pure benzene, toluene and xylene is aimed at, the crude benzol is separated into three fractions, each of which is submitted to the washing treatment separately in order to economize in the use of acid. As regards the type of still and condenser employed for this "fractionating" of the crude benzol, a column provided with "bell-lutes" is preferable to the perforated-plate type, since the holes in the plates are liable to get stopped up with rust or other matter. Hamer, in the paper already quoted, however, recommends for this stage of the rectification process the Gasser type of still, and states:

> The working of the primary still should be as slow as possible for the first or forerunning fraction. The water overflow of the analyzer should show a temperature of at least 10 deg. C. lower than the normal reading for the benzol fraction. (This temperature varies for the different types of apparatus.) The rate of flow of the condensed products should be fixed about half the normal rate. By these means a large proportion of the unsaturated hydrocarbons and carbon bisulphide are removed as the forerunning fraction.

On the subject of washing the "once-run" products, Hamer's paper is also worth quoting:

> The first washing is usually a preliminary wash of from 5 to 10 gal. of D.O.V., according to whether the size of the charge is 1000 or 2000 gal. The object of this preliminary wash is to dry the benzol thoroughly; it also serves to remove pyridine bases, and to some extent attacks the more easily decomposed unsaturated hydrocarbons. Half-an-hour's brisk agitation of this first wash of sulphuric acid is ample, after which a period of one hour is allowed for settling, and the acid is then run off as completely as possible. A further quantity of acid is then run into the washer, equivalent to 2½ to 3 per cent. by weight of the charge; agitation is maintained for at least an hour, and during the period allowed for settling a sample is taken and tested.
>
> The quantity of acid required for the first or main acid wash largely depends on the care taken in, and the efficiency of, the once-distilling operation. Where washing in bulk of the once-run benzol is the practice, it will generally be found that a further additional wash of about 2 per cent. of acid is required to produce a clean rectified benzol.



After the treatment with and removal of the acid, the charge is washed four or five times with water by spraying onto the benzol and allowing it to fall in the form of a fine rain. Finally, treatment with a 10 per cent. caustic soda solution is given, followed by two further washes with water.

PLAN OF BENZOL RECTIFICATION PLANT AT MITCHELL MAIN COLLIERY CO. COKE OVENS

This chemical treatment takes place in large cast-iron tanks of 1200 to 2500 gal. capacity, provided with mixing appliances of the inverted cone or archimedean screw type. In cases where old boilers are used for the purpose, it is necessary to have them lead-lined. Cast-iron gland cocks are best for the run-off pipes, since other metals will not stand the action of both sulphuric acid and caustic soda.

The final rectification of the washed crude benzol, or of the fractions into which it has been separated, is carried out on similar lines and with similar distilling and condensing apparatus, to that used to obtain the once-run products. When pure benzene, toluene and xylene are required, the first rectified products are re-

ELEVATION OF BENZOL RECTIFICATION PLANT AT MITCHELL MAIN COLLIERY CO. COKE OVENS

washed with chemicals and water. Special precautions must be taken to remove the thiophene and other sulphur compounds which are the chief cause of trouble at this stage.

One of the latest methods for this purpose is to treat the benzene with cold chlorine gas. Chlorine has a greater affinity for thiophene compounds than for benzene and toluene, and as the chlorine derivatives have a much higher boiling point than pure benzene and toluene, selective treatment with chlorine offers a simple method of separation. According to Hamer:

> In tests made last year of this process, after the use of 1½ to 2½ per cent. of chlorine, the benzene gave no reaction with isatin, although it previously contained 0.1 per cent. thiophene. By means of two rectifications, preceded in each case by efficient sulphuric acid treatment, there is seldom much difficulty in obtaining a "pure" benzene of the standard required by dyemakers and explosives manufacturers. In the case of toluene it is rather more difficult to produce the pure article. For one reason, both paraffins and unsaturated hydrocarbons are present, which have boiling points too close to that of toluene to permit of much purification by fractionation.
>
> The washed rectified toluol should be collected over a range of 105 to 120 deg. C. It is then washed with Nordhausen sulphuric, or with D.O.V. of 1.84 sp.gr., having an addition of 1 per cent. nitric acid. After drawing off the acid, the toluol is washed with caustic soda solution, followed by clean water. Washed toluol has a tendency to emulsify with water, so that care must be taken in adding the final water washings that violent agitation does not take place. The washed toluol is then fractionated and the portion collected boiling over the limits of 108 to 114 deg. C. This material will still contain benzene, xylene and paraffins which are not nitrifiable. Without additional washing a further careful fractionation will yield on a good column 80 per cent. pure toluene from this twice-washed and rectified toluol.

In conclusion, a description of the benzol rectification plant at the coke ovens of the Mitchell Main Colliery Co. may be given. The details are taken from the paper by Walmsley and Morley previously quoted. The crude benzol is pumped from a storage tank, into an agitator, which is of wrought or cast iron and of 1200 gal. capacity. In this tank the washing with sulphuric acid, water and caustic soda is carried out with the aid of mechanical agitators. After settling, the various wash liquids are run off by means of a suitable cock.

The washed benzol is then pumped out and passes to a still, which is fitted with a closed coil for dry steam heating, and a perforated pipe for blowing live steam into the liquid when required. The charge of benzol is first heated by the closed steam coil, and the vapors which are produced pass to a fractionating column. The vapors which escape from the head of this column then pass to a condensing coil, where they are cooled to the liquid form and atmospheric temperature. They then pass to a separator, where any water present is removed.

As the distillation proceeds, live steam is gradually admitted to the still to carry over the vapors of higher boiling points. The liquid which is finally left in the still is run off into a settling tank, where any naphthalene it contains settles out in solid form. The various fractions of the distillate as they run from the separator are collected in 50-gal. drums. The contents of these drums are tested in the laboratory before mixing to produce the following standard products: Benzol, 95 per cent. over at 90 deg. C.; toluol, 90 per cent. over at 117 deg. C.; solvent naphtha, 90 per cent. over at 160 deg. C.; heavy naphtha, 90 per cent. over at 190 deg. C.

Chamber of Commerce to Consider Reconstruction Problems

MANY phases of reconstruction will be taken up at the Reconstruction Conference of Industrial War Service Committees called by the Chamber of Commerce of the United States for Dec. 3, 4, 5 and 6 at Atlantic City, N. J. The sudden termination of the war has brought reconstruction to the front as the one important problem today facing business men. In the congress of business interests at Atlantic City an opportunity is offered for industry to advise the public as to those questions which primarily affect business.

The program for the conference has not been completed, but enough of the details have been worked out to indicate the comprehensive way in which this conference will approach the problem of reconstruction. On Dec. 3, the first day of the conference, the 350 war service committees meeting separately will take up questions of special interest to their own industries. At these meetings there will be formulated the policies of the industries represented by the committees and resolutions which individual crafts desire to present during the conference.

For the purpose of facilitating discussion and coördinating the ideas of the various industries represented, the war service committees after meeting separately will gather together in 35 related groups. Afterward these related groups will assemble as ten major groups representing the ten primary industries within the United States.

The ten groups as defined for the purpose of the conference are as follows: Food products, textiles, heat, light and power, metals and minerals other than iron and steel, iron and steel, wood and wood products, chemicals, leather, earthen products and industrial professions. One of the 35 related groups is "coal and coke." A list of 25 questions has been sent out by the War Service Executive Committee to the members of all war service committees for use as a basis for the deliberations of the individual war service committees at their first meeting. These suggestions are not considered exhaustive, and members of the committees have been requested to present other subjects which they think should be discussed. The subjects are set forth in the following communication to the committees:

1. What legal methods or means, affecting the appended items, could be introduced in the craft to better stabilize prices, during the reconstruction period.

a. Inventories on hand.

b. Orders placed at war prices but not delivered.

c. Labor costs and conditions.

d. Increased taxes.

e. Increased rates of interest.

f. An estimated increased demand for non-war materials restricted during the war period.

g. Will an increased production of your commodity increase the price of material or labor, or will a controlled redistribution of material and labor from war industries prevent such an increase?

h. Discuss the practice of the sale of commodities at a price less than the cost of production; its injury and disturbance on the industries and the ultimate consumer. What methods would you suggest to remedy this evil?

i. If the Government sees fit to dispose of used materials and products in the open market, what effect will it have on your production and the sale of new goods? At home? Abroad?

j. If it is not advisable for the Government to sell these goods on hand, either home or abroad, what shall it do with them?

k. In this connection, what point of contact should business interests have with the Governmental departments in the sale or disposition of these various commodities?

2. What is the estimated amount of labor, skilled and unskilled, male and female, required for the estimated 1919 production? What is to be the source of labor? How much must be moved? How much have you lost to war industries?

3. What is your financing problem during the reconstruction period? Do you recommend Governmental aid? Is financial legislation needed? Should the Capital Issues Committee be continued during this period?

In this connection discuss and recommend what financial obligations, if any, the industries in your craft are under to the Government for moneys advanced for buildings, machinery or as loans or security for Government contracts. How are these to be liquidated or adjusted?

4. What method would you suggest for the cancellation of Government war orders with your craft, that would create the least amount of hardship on the industries and permit a readjustment to normal commercial conditions?

5. On undelivered Government orders, what percentage of materials on hand, supplied either by the Government or purchased by you for these Government orders, can be utilized by your craft for commercial purposes during 1919? What disposition shall be made of those not usable?

6. Have you any suggestions to make as to the continuation of the War Industries Board or any of its divisions, or any other Governmental departments during the period of reconstruction, such board or departments to have the authority to control materials and regulate prices? If so, for what period?

7. What intelligent control of materials during the reconstruction period could the War Service Committee suggest which would prevent an over or under supply and avoid a demoralization of the market? Should this be controlled by the crafts or by a Governmental agency?

8. What effect had the war program on your output? Was it increased or decreased? Will there be an increased demand during the reconstruction period? If materials are uncontrolled will prices go up or down?

9. What is the estimated tonnage or unit of production of your raw materials for 1918? For 1919? Estimated demand for foreign commerce for 1919?

10. What is the estimated demand for your finished product for 1919? How does this compare with the average demand per annum in weight or unit of production for a five-year period immediately prior to 1914?

11. Sources of your raw materials? Domestic or imported? If domestic, can railroad cross-hauling be eliminated by purchasing nearer your plants? Causes of cross-hauling? If imported, at what ports? Would other ports of entry be more advantageous? What ports and why?

12. The value of a uniform method of cost accounting for the individual manufacturer and the craft as a whole.

13. What suggestions of the Conservation Division made to your craft might, with financial profit to your craft, be continued during the readjustment period? Is it possible to maintain a conservation schedule after the war, without legislative authority?

14. What methods and practices, other than those your craft has already introduced, would simplify production, save materials, eliminate wasteful practices, reduce the number of styles, without destroying individual creativeness?

15. What propaganda are necessary to educate the retailer and consumer to accept these eliminations and simplifications, and what plans might be arranged for better functioning with committees of jobbers and retailers handling your commodities?

16. What percentage of the commodities represented by your war service committee was produced in the United States before the war and what percentage imported? What suggestion have you to make for increased production for domestic and foreign commerce?

17. What effect will foreign competition have on your business? Will it increase or decrease your production?

18. What is the underlying reason for the importation of foreign-made goods—Prices? Styles? Label? Design? Or excess demand over domestic supply?

19. What disposition should be made by the Government of her merchant marine?

20. What steps have you taken, or do you propose to take, for the entire craft to take advantage of the Webb-Pomerene Bill, which allows combination for foreign trade, or have you other plans? What do you suggest as the best means of financing foreign credits? What percentage of the foreign commerce heretofore controlled by Germany can your craft obtain and supply?

21. What study is necessary, and what suggestions have you to make, in order to determine what are the needs of our allied countries for rehabilitation, and how far can you supply both raw and finished materials until they have been rehabilitated?

22. Has your craft been solicited by, or are you soliciting, foreign countries to supply these materials for rehabilitation purposes? If solicited, does this come from the Allies, or from neutral or enemy countries?

23. Would you recommend the appointment of a committee of United States manufacturers to confer with similar committees from our Allies, to learn of their plans for protecting industry during the reconstruction period? Also to obtain information regarding commodities and supplies needed by them and ourselves during this period.

24. When the demobilization of military forces takes place, how can these men best be returned to their former industrial pursuits, and how will it affect your labor situation?

In this connection, how closely should the conference work with the Governmental bodies in the study of demobilization plans?

25. What suggestions have you to make to encourage and stimulate public work, such as the building of roads, pavements, water and sewer extension, the construction of public buildings, schoolhouses, etc.? What effect will it have on the labor market?

In this connection consider the building program in the United States and especially the utilization or destruction of new plants built for war purposes. Location of convalescent and reconstruction hospitals near industrial centers, so that these men can be trained in the factories nearest to the hospitals without creating new vocational schools.

The committees are anxious to receive from industry such information and advice as will enable them to properly mirror the attitude of the industrial world to business problems. Such communications from the coal and coke industry may be sent direct to the Coal and Coke Committee of the Reconstruction Conference, Atlantic City, N. J., or can be sent to *Coal Age* for submission to the proper committee on Dec. 3.

Experience has shown that in the United States the normal balance in transportation which brings about a maximum of production with maximum economy occurs when out of every 100 tons of originating freight approximately 56 tons are unmanufactured mineral products and 44 are manufactured products, foodstuffs and other commodities, and when of the 56 tons of mineral products 35 tons are coal. Of these 35 tons of coal the railroads themselves consume about 12 tons.

Coal Mining Institute of America

The Coal Mining Institute of America will meet Dec. 4 and 5 at the Fort Pitt Hotel, Pittsburgh, Penn., opening with a question box presided over by Vice President Fohl. The questions are as follows:

1. Are roller bearings too delicate for coal-mine cars?
2. What are you doing to increase the efficiency and steady working of your employees? With what success are you meeting?
3. In what ways can the conservation of materials and supplies be best effected both inside and outside the mines?
4. Is the underground use of alternating current more hazardous than the use of direct current?
5. Has the law permitting the employment of non-certified officials in coal mines been detrimental to their efficient and safe operation?
6. Is there any practical way of dealing with a drunken miner who is above the draft age or one who has been given deferred classification through some other cause than an industrial claim?
7. To what extent can the water-gage chart be used as an index of the volume of air passing through a mine?
8. Should the drawing of mine timbers be penalized under the safety standards in computing compensation insurance rates? If so, under what conditions?

At the dinner, which will take place on Wednesday evening, Dec. 4, S. E. Button, chief of the Pennsylvania Department of Mines; J. B. Neale, Federal Production Manager, and W. R. Rasmussen, of the National Safety Council, and several representatives of the Government will be present, including, if it can possibly be arranged, Franklin K. Lane, Secretary of the Department of the Interior.

On Thursday E. N. Zern will give an address on "Loading Machinery in Coal Mines"; K. W. Mackall, on "Use and Abuse of Headlights on Mine Locomotives"; K. C. Barth, on "Preservative Treatment of Mine Timbers as a Conservation Measure"; J. C. Davies, on "Reopening a Mine Following a Mine Fire," and John Andrews, Jr., on "Power Losses Inside the Mine and How to Correct Them."

Legal Department

MINER'S WORKING PLACE — A track in a mine used for removing coal in the pulling of pillars, but not as a usual means of going to and from work, was a part of the working place of a miner engaged at work there and not such "traveling way" as obligated the operator to keep the place safe from falling rock. (Colorado Supreme Court, Rossi vs. Calumet Fuel Co., 173 Pacific Reporter, 943.)

USE OF DANGEROUS TOOLS IN TAMPING CHARGES.—A coal operator is not liable for injury to a miner, caused by premature explosion of a charge of powder which the latter and his helper were shoving into a drilled hole by means of a steel tamping bar, where the injured man was a certified miner, had had several years' experience in mining, furnished his own tools, and had just as good means of appreciating the danger to which he was exposed as did his employer. Under such circumstances, the employer cannot be regarded as having been negligent in permitting plaintiff to use the particular bar. There is a general rule of law to the effect that where one obtains employment by holding himself out as being skilled in his trade, he cannot afterwards assert negligence on the part of the employer because of failure to instruct him in matters which men so skilled are presumed to know. (United States Circuit Court of Appeals, Second Circuit; Sawickas vs. Lehigh and Wilkes-Barre Coal Co.; 247 Federal Reporter, 432.)

Work Started by Fuel Administration May Be Kept Alive After Peace Is Declared

Definite recommendations have gone to the President from the four great war agencies—the Fuel Administration, the War Trade Board, the War Industries Board and the Food Administration—as to those of their functions which should be continued. These recommendations have not been made public. So far as the Fuel Administration is concerned, however, it is fairly well understood that the continuation of the zone system, of the conservation work and of the statistical compilations has been recommended.

So far as can be learned there is no intention of trying to keep the Fuel Administration alive after the expiration of its legal existence. The continuation of the zone system probably will be in the hands of the Railroad Administration. Conservation and statistics also can be handled by existing governmental agencies. In both these divisions the Fuel Administration has made a remarkable showing. No less than 11,000,000 tons of coal are being saved annually, it is stated, as a result of the conservation efforts of the Fuel Administration.

Coal statistics, prior to the war, were handled largely by the Geological Survey. Some work along that line was done by the Bureau of Mines. In neither case, however, were the appropriations for the work at all adequate for comprehensive compilations. By close cooperation with the statistical bureaus of private enterprises, especially the railroads, a considerable number of very valuable statistics was made available. Since the war, however, the railroad statistical bureaus have been discontinued. Some of the bureaus maintained by coal operators have been discontinued. As a result, the Government could not do justice to the industry in allowing no larger expenditure for statistical work than was the case before the war.

Zoning System Saving Millions

Estimates made earlier in the fuel year, that approximately 160,000,000 car-miles would be saved in the coal year through the operation of the zone system for the distribution of bituminous coal, are being fully realized, it was announced on Nov. 16 by the United States Fuel Administration.

This system, made possible through the close coöperation of the United States Railroad Administration with the Fuel Administration, has had a large share in bringing the nation's supply of bituminous coal to its present proportions, which, with patriotic economy, will be sufficient for the winter's requirements.

This method of distribution was established so that the coal supply of all sections of the country should normally be derived from mines relatively near, thus preventing abnormal and wasteful transportation movements, and insuring more equal distribution of cars to the mines and the more steady employment of mine labor.

Early estimates were that the movement of bituminous coal affected by the zone system would involve about 300,000,000 tons, or 60 per cent. of the total production. The latest figures show that 368,858,000 net tons of this kind of coal have been produced and delivered since Apr. 1, 60 per cent. of which is affected by the zone system.

These later figures show that even more than the originally estimated 160,000,000 car-miles will be saved in round trips to and from the mines and that considerably more than the 300,000 additional trips, which the saving in car-miles would effect, will be made. Exact figures have not been compiled, but the early estimate allowed for the 300,000 additional trips being the equivalent of 5 per cent. increase in the production.

Fuel Administration Issues Warning

A tendency in some quarters to take it for granted that the war is over, and that therefore all bars are down, has made it necessary for the Fuel Administrator to issue the following warning:

"In order that there may be no confusion or misunderstanding, the United States Fuel Administrator wishes it understood that the signing of an armistice in no way alters the rules and regulations or the supervision now in force. By Act of Congress the Fuel Administration continues until the promulgation of the treaty of peace and its powers extend to the production, distribution and conservation of fuel, including fuel oil and natural gas. Due notice will be given of any cancellations or changes in orders and regulations by the duly authorized officials of the Fuel Administration in Washington."

Applications for mine sidetracks are to be made "as in pre-war days," the Fuel Administration announces. This is believed to be the forerunner of the relinquishment of certain other powers which have been exercised by the Fuel Administration. More than 800 applications for sidings and auxiliary tracks have been handled by the Fuel Administration. Most have not been granted.

Transportation Conditions Generally Satisfactory

Reporting to the Railroad Administration on transportation matters the Fuel Administration has made the following observations:

Eastern, Allegheny and Pocahontas Regions—Transportation ample and surplus car supply, except on Baltimore & Ohio R.R. Some little difficulty on the Chesapeake & Ohio R.R. and Monongahela R.R.

Tidewater—Vessel and car supply ample.

Lake—Bituminous program completed and shipments discontinued Nov. 16.

Southern and Western Regions—Transportation and car supply ample. Movement slower account influenza.

Coke—Beehive production stationary. Byproduct production somewhat reduced.

General—Coal production further reduced account illness and elections; but bituminous supply ample throughout the country.

The Railroad Administration also has made public that "Utah coal mines are running on short time on account of the lack of orders," and that "shortage of labor has delayed the loading of cars at mines in the Pocahontas region and has delayed dumpage at tidewater."

Formal Order Closing Lake Trade

The text of the order with regard to the closing of navigation on the Great Lakes is as follows:

"Except in individual cases where shippers have unfilled obligations for coal needed for special uses, and such shippers can assemble cargoes rapidly enough to avoid delay to railroad equipment and vessels assigned for this particular coal, all loading of bituminous coals for Lake Erie ports will be suspended with the close of business, Saturday, Nov. 16, 1918.

"Except for the individual cases named above, all loading of cargoes of bituminous coal at Lake Erie ports will cease at midnight, Saturday, Nov. 23, 1918.

"Definite arrangements must be made in advance with H. M. Griggs, Manager Ore and Coal Exchange, Cleveland, Ohio, by shippers desiring to forward cargoes after that date for use of car dumping machines at Lake Erie ports, as the existing pooling and loading arrangements of the exchange will be discontinued at midnight Nov. 23.

"Shipments of anthracite coal to the Upper Lakes will be permitted to the extent of the regular allotment as previously determined by the United States Fuel Administration under individual arrangements between shippers and carriers for the floating of this coal up to the date of the closing of the lake navigation."

Await Return of Fuel Commission

Return of the Fuel Administration's Commission, which now is in Europe, is being awaited with much interest. As yet, the Commission has cabled none of its observations and it is regarded as probable that no report will be made until its return, which is expected about Dec. 20.

Prior to the return of the Commission, it is not probable that the matter of extending aid in the rehabilitation of the French coal mines at Lens will be gone into deeply. It is understood that the French Government already has in storage here a considerable quantity of coal-mining machinery. This machinery was purchased two years ago, when it was thought the Lens regions would be liberated. Further purchases of machinery for this purpose are being negotiated, it is said.

The introduction of American mining machinery into French and English mines is expected to open new markets to American machinery manufacturers. Conditions which have interfered in the past in the use of machines in English coal mines are changing, it is believed. No objection on the part of French labor to the use of machines is anticipated.

Fuel Restriction Modified in Cement and Clay Products Industries

Percentages of curtailment of fuel to be used in the manufacture of clay products and cement have been cut in two. This action has been taken by the Fuel Administrator in view of the increased supply of bituminous coal now available. Under present conditions, fuel curtailment in the industries mentioned must be the following per cent. less than normal requirements: Cement, 12½ per cent.; face brick, common brick, paving brick, terra cotta, roofing tile, floor and wall tile and sanitary ware, 25 per cent.; hollow tile, drain tile and sewer pipe, 12½ per cent.; stoneware, 7½ per cent.

Price Fixed on Steam Sizes of Anthracite

Prices of steam sizes of anthracite coal are to be held below the pea size price. The order to this end reads as follows:

"On and after the effective date of this order (Nov. 17) the maximum prices for the different sizes of anthracite coal below and smaller than the size commonly known as 'pea' size, f.o.b. mines, shall not be in excess of the maximum prices established and in force, on the effective date of this order, by Executive Orders of the President and orders of the United States Fuel Administrator for that size of anthracite coal commonly known as 'pea' size, less 50c. per gross ton of 2240 pounds."

Coal Loaded During Week Ended Nov. 2

Loading of coal during the week ended Nov. 2, with the figures for the corresponding week of 1917, is shown by the following:

	1918	1917
Total cars bituminous	187,638	187,184
Total cars anthracite	29,223	31,115
Total cars lignite	3,530	4,134
Grand total cars, all coal	220,391	222,433

The decrease in coal loading has been due to influenza among the miners and railroad workers. Total increase of 1918 up to and including week ending Nov. 2, over the same period in 1917, is 723,047 cars.

A reduction of its allotment of bituminous coal has been asked for New England by the Fuel Administrators of that section. The original budget assigned 30,000,000 tons of bituminous coal to New England. It is now asked that shipments not exceed 27,300,000 Deliveries up to Nov. 1 approximated 17,000,000 tons.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The week has been quite generally without any outstanding events, and indeed it is well that it is so. More important than any other matter is the necessity for stability at these times. We need a pivot about which to turn when retreating from war to peace. We do not want to change any of the conditions which do not need change, until we have completed all those changes which cannot be delayed.

The soldier and munition worker must go back to civil work, and business must be kept steadily going so that he can find his place still open to him in the files of industry. We must be all in line and at attention waiting for him when he comes. After he is back, and things moving steadily, then we can attack other problems. There is such a thing as trying to achieve too much. It is fortunate that there is a larger element trying to secure stability in industry than trying to upset the present regimen.

LET OUR SLOGAN BE "STAND BY THE PRESENT"

We must try just now not to rock the boat. The soldiers and munition workers crowding into the front, rear and oar seats of the industrial craft will rock it badly enough; the turning of the rudder so as to direct the boat from war to peace will also tend to upset it. If those who are waiting for the soldiers and munition workers add to the confusion by seeking new adjustments in the industrial craft, then the dangers of an upset will be multiplied. For the moment let us cry as loudly "Stand by the present" as we have cried in the past "Stand by the President."

The mine workers and operators somewhat generally are realizing their duty at this time. They are not going to engage in a conflict at a juncture so critical as the present. Some time ago the operators quite generally thought that the wages being paid were war-time wages to be adjusted later, but now they realize that war-time wages and largely also war-time prices have come to stay. The peace industries, or rather those which are principally in evidence in peace, are quite largely nonunion, and, as resumption takes place, they will have to bid for labor as war industries have, and they will have to pay the price. They will accordingly come up to a standard in accord with the cost of living.

Great Britain, France, Belgium and Germany—pardon our mentioning them together—will, we may expect, increase wages till they reach our level. In that event we shall not find their competition heavy unless we endeavor to enter places where, by reason of unfavorable transportational difficulties, we are placed at a disadvantage. When the world is levelled let us level it up rather than down.

HAYES STILL DEMANDS A NEW WAGE SCALE

Frank J. Hayes, the international president of the United Mine Workers, on Nov. 15 delivered a statement condemning lowering of wages—which was right—but urging increases—which was wrong. Those who have not had increases during the war or whose increases have been small may be justified in looking for the mine workers to pay them more money, but they strongly resent the action of those men who claimed and got big wages because their work was essential to the war and who now want still bigger wages when peace comes along. Let them go back into the corner of the field and let the others take their place at the trough. It may be added that all authorities do not agree with Mr. Hayes that there is no likelihood of prices declining for a year. They may decline enough to send profits aglimmering. They will not lower markedly, however, for they are based on high wage scales which will not, we hope, be lowered. His statement is as follows:

"Wages have gone up during the war, but they have not advanced proportionately to the increased cost of living. All authorities agree that there is no likelihood of prices declining for at least a year. But despite this prophecy, councils of employers are now devising programs to batter wages down. It is this scheming that organized labor must combat. We cannot parley, linger, wait. Our forces must be up and doing, not only to thwart attempted reduction, but to win additional gains to meet living costs which present-day wages are so inadequate to cope with."

GOODWILL NEEDS NO CITIZENSHIP TICKET

The war being over let us not give up our Americanization plans. Nothing will make more for unity than to have us all think and speak together. For this, education is necessary. Let us avoid trying merely to make citizens. The last matters in Americanization are the possession of a court certificate and the singing of the "Star Spangled Banner." The first matter is the creation of a kindly feeling of appreciation. This appreciation can only be attained by friendliness and understanding and the understanding can only come to one who knows the tongue of this country. Given the friendly understanding, the national anthem and the certificate of citizenship will follow as a natural development. Every mining plant should have its English school, and every man who cannot speak English should be compelled to attend it. It would be well if in addition common branches of education should go with the other instruction. It would pass belief if hearing the record of the national life and achievements accompanied by the glad hand of the instructor failed to give the same intensity of passionate affection for America that is deep-seated in the heart of the native born.

In central Pennsylvania a somewhat bitter dispute has arisen as regards the Fuel Administration's request that the mine workers should work on Sunday, Oct. 27. It will not be made any less bitter by the sudden change in the coal situation from a small threatened shortage to a large surplus. The Fuel Administration did what it believed was for the best. It denies that it asked the men to violate the contract regulations in order to increase tonnage, as the contract did not make any reference to the observance of Sunday as a holiday. This is, of course, more or less of a subterfuge. The union officials declare they were not consulted and that something should have been said to them.

RIGHT TO SUNDAY REST IS NOT JEOPARDIZED

No harm has been done; rather a great good. The mine workers have been afforded a chance to show their local devotion to the national interests, and the contract stands just as rock-ribbed as ever. No one will ask for Sunday work from the miners now that an armistice is declared. Sunday work is so at variance with the movement of the national conscience that nothing but the war and the scarcity it causes will be held to justify any such activity.

Labor news is extremely scant, but as has been heretofore suggested all that comes to hand is good. From Conifer, a mine of the Allegheny River Mining Co., in Armstrong County, central Pennsylvania, we hear of a miner, Rudolph Cheney, who loaded 438 tons of coal during the month of September, or an average of 18 tons per day for every working day in the month.

West Virginia reports that the influenza epidemic is rapidly receding throughout the state except in a few spots where it made its attack somewhat late. The productive ability of the mine workers is still, however, restricted

owing to the weakness which an attack of influenza leaves as its wake. In the Fairmont region, now happily bidding farewell to the disease, the epidemic made a surprise visit to the Annabelle plant of the Four States Coal Co., and several went down before the infection.

The influenza epidemic was quite late in reaching Wheeling and the Pan Handle of West Virginia, arriving there within the last few days. A report from Moundsville, Marshall County, a few days ago stated that the epidemic was worse at that place. The epidemic invaded the settlement of the Youghiogheny & Ohio R.R. mines near Martins Ferry on Saturday, Oct. 9, in most malignant form, three deaths resulting in a few days.

The epidemic of influenza which took a heavy toll in Logan County during the last month is now believed to have been entirely checked. Dr. Hess, the Government physician, is still at work in the mining camps, but regards the situation as safely past the critical stage; and he is therefore devoting most of his efforts to securing better sanitary conditions in some of the camps.

The epidemic in West Virginia seems to have been, at all times and places, mild compared with that in certain parts of Pennsylvania. If reports are true Wishaw, a town in Jefferson County with 400 inhabitants, has had 78 deaths since Sept. 28. There were probably only four English-speaking families in the little village. The rest spoke Italian and were of that nationality. Of the 400 all but ten were victims of the epidemic.

Much Ado About Nothing Costs $12 a Head

As a result of the efforts of Special Umpire Allison O. Smith, representing the Fuel Administration, the dispute has been settled between the McKell Coal Co. and its mine workers at Kilsyth, on the line between Raleigh and Fayette Counties, West Virginia. The difference was as to the hour at which the man trip should leave the outside of the mine. The hour is fixed at 7 a.m. The company and mine workers were at loggerheads about this trifling matter for 30 long days. Every miner was fined $12 for going on strike in violation of the express terms of the contract.

The influenza has made heavy inroads into the funds of the United Mine Workers in the State of Illinois. In one day recently 19 claims were presented at the offices of the organization in Springfield. The beneficiaries of each member of the organization who dies are paid $250.

The Illinois organization can stand the drain, however, as it still has $2,434,841 in the bank. The Illinois district has 95,000 members and is the largest and wealthiest miners' union district in the world. An audit of its accounts which brings the record down to October has just been completed by the district auditors, J. H. Pitman, James Box and Homer Whiteside. It shows that the income of the organization in the district for the preceding six months was $723,612 and the expenditures $252,782. The balance on hand at the beginning of the half year was $1,963,958, to which $470,884 is added as the excess of income over expenditure for the half year. The largest item in the income tables is that of assessments, which brought in $612,243.

Biggest District Pays Out Big Money

In the expenditure tables the largest item is death claims, for which $127,728 was paid out during the half year. For relief and aid $2154 was paid out. Officers' salaries amounted to $38,082 and their traveling and other expenses to $22,325. Field workers' salaries amounted to $10,317 and their expenses were $2408.

Of the funded assets of the district $500,000 is represented by Liberty Bonds. The district has real estate in East St. Louis and Chicago valued at $139,000. Two thousand dollars are invested in the bonds of township schools.

Numerous loans, some of large dimensions, have been made to related organizations, locals of the district and cooperative organizations. The largest loans are $100,000 to the Western Federation of Miners and $100,000 to District No. 6, United Mine Workers. The greater part of the funds are invested in 67 banks, all but four of which are in Illinois. The four outside banks are in Colorado and hold $50,000 among them, and this money is guaranteed by the international organization. Six of the Springfield banks have deposits ranging from $25,000 to $150,000. The district organization owns only $830 of war stamps.

Little coal was mined in Illinois on Nov. 11, when the news of the ending of the war came. The mine whistles helped spread the tidings, and the miners, instead of going to the pits, formed in parades and marched through the streets of the town. The suspension was much more general than on the previous Thursday, when a premature announcement was received, because that announcement did not come until about noon and most of the miners were below. When the real news came it was so early in the morning that all the miners knew it before going to work, and so they were able to observe the event. Influenza, coupled with the peace holiday, has greatly cut down the production. At some mines the man power has been reduced 50 per cent. by sickness, death and fright. Many miners are laying off until the epidemic subsides.

Illinois Miners Want Wage Readjustment

With the signing of the armistice some people expect that the Illinois miners will become more insistent in their demands for increased wages. This expectation has given rise to speculation as to whether they will consider that they are bound to still observe the contract which was to run for the period of the war. It is supposed that there will be a disposition to claim that the war has ended, for the purposes of the contract, although peace has not been signed.

From Roundup in Montana word comes of a great shortage of coal miners and other coal mine workers. As a result of the scarcity a much lower production has been mined this year. The consumer will doubtless suffer where he is dependent on the Roundup output. The state director of the United States Employment Service, Scott Leavitt, has been asked to provide the men needed.

A vote of approximately 4300 coal miners in the State of Washington has resulted in Martin J. Flyzik, president of District No. 10; Ernest Nesham, secretary-treasurer, and Sam Caddy, of the international executive board, of the same district, being reëlected. President Flyzik is now in the East seeking an increase in wage for the Washington coal miners and the matter will be taken up with President Wilson direct.

Like Dynamite To Be Handled with Care

On Nov. 7, Burton L. French, a representative from the state of Idaho, introduced into the House of Representatives a joint resolution, No. 342, which was referred to the Committee on Appropriations. It provided for a commission of seven members to be known as the United States Employment Commission, and authorized them to spend a sum of $50,000 in the making of plans for road building, canalization and improvement of rivers, drainage, reclamation of lands by irrigation or otherwise, reforesting of acres chiefly suitable for forest and other improvements of large community or national interest.

The commission is to report to the President as early as practicable as to the importance of the work planned, the number of men that can be advantageously employed and, as nearly as may be practicable, the kinds and character of labor required and any other pertinent facts.

This is a splendid scheme to cushion the possible blows of reconstruction should any such occur. The plans should be, however, marked "Dangerous! Handle with Care!" for if they go off prematurely or in the neighborhood of pressing business they may do a lot of harm. We must always remember that the work of this committee should be looked upon as merely a safety inlet valve and as such it should not be opened unless the vacuum in the labor market becomes too high. Moreover, there is always the danger that it may develop into the largest pork barrel ever unstaved and disembowelled in our, or any other, history.

On Nov. 19 Frank P. Walsh, joint chairman with W. H. Taft of the National War Labor Board, tendered his resignation to President Wilson.

EDITORIALS

Fighting Publicity with Publicity

VIGOROUS indeed are the attacks made on the coal industry both in war and in peace. Some of its contemners find fault with the financial side of the industry; others attack it from a labor viewpoint. The men and the women who denounce the industry boldly sign their names to their diatribes, usually appending even their given names, and as a result the public gets to know them, to acquire a certain familiarity with them, and is then ready to listen to all they have to say. The people delight in the pungency of their remarks and believe much of what they put into print. How can the readers of their writings do otherwise, for knowing nothing about the industry they have no information wherewith to meet the misstatement. With no one to contradict the traducers of our industry, even anonymously, everybody believes that their arguments are unanswerable.

How much better it would be if there were men in the industry who were as well known to the public as these hireling publicists and who yet acted in the rôle of honorable and conservative protagonists of the coal operators. Should some of the men in the industry thus enter the public eye they could unquestionably remove with success much of the criticism under which the industry rests and prevent the development of the growing discontent.

The public is not to blame if it adjudges that the sullen silence, which the coal industry deems the wiser plan, is the outcome of guilt rather than of reserve.

Some time ago the anthracite operators in council assembled prepared advertisements which were published far and wide. It is not to such publicity that we are referring but rather to written statements of individuals such as are in general known as "interviews." Those who make such statements before long learn just what papers will publish them without unfair modification.

Yet it seems premature to talk about interviews in the daily papers, for operators have scarcely arrived at the point where they will, under their own names, discuss, in the technical press, the problems of industry, ethical or even mechanical. They are afraid to take a stand for fear it will be criticized. The temperately minded, with a few admirable exceptions, will not write even anonymously. Still fewer are the broad minded men who will sign their names to the thoughts they commit to paper.

Thus while the rabid element in the industry is suffered to misrepresent the purposes and ideals of the mining world, the radical element outside the industry makes false and unfair attacks on it. All the while there are none to defend it either from Bourbonism within or Bolshevism without.

If the thoughtful men of the industry would only do their thinking out loud. If they would publish their conclusions without fear or restraint, we might in a short while arrive at a better understanding. A few false steps might be taken, but no false step is as bad as no step at all. The silence of the industry appears to all the world as ominous. It seems that there must be something to hide when men are so little willing to put their thoughts on print paper.

Coal Industry's Production Manager

THE war being apparently ended it is time to take stock of the big men it has given us. Happy indeed was the chance that lighted on J. B. Neale for production manager. To him we owe a great deal, for it was largely his enthusiasm which brought up the production despite the loss of men to the united services and to the munition works. He truly became a leader in the industry—a vital force in promoting adequate coal production.

Leaders of men are men who can sway moral forces, those qualities in men we too often scoff at and decry; those qualities which, deny them as we may, are the very breath of the nations. Neale believed so firmly in the moral call that he could always appeal to it effectively.

His was no easy task; so hard indeed was it that we still find ourselves greatly wondering how he contrived so readily and happily to perform it. He had to direct two forces who, when they were asked to act in unison, usually ended by scrapping among themselves. The word "production" always held endless possibilities for a purposeless squabble. Somehow, however, Neale managed to harness capital and labor to the national gun carriage as a splendid working team, with the steeds eyeing one another occasionally perhaps, but pulling for all they were worth.

To most men there were two ways in which the work could be done. Neale could have "jollied" both of the contending parties, or he could have been indiscriminately neutral and with foolish words condemned both parties for the follies exhibited by either—a balanced form of denunciation which of late has been all too common. Neither of these courses did Neale take. He would have looked upon mere "jollying" as the shallow and dishonest concept of a politician, and he would have regarded neutrality as an unworthy trick of a man without convictions.

Instead of taking either stand he used his close-hand knowledge of the coal business in such a manner that every word of blame—and words of that kind were many—were as soon as uttered recognized as just and truly spoken. Instead of blaming both operators and mine workers for the same faults, he singled out their peculiar failings for correction. He made each of them make careful inventory of their failings and record them in black and white. It was no secret confessional either; he would have the outcome of it all posted in

plain sight where all could see how much time and tonnage were lost by the faults of each.

To the credit of both parties, be it said, they took his advice well, and they prepared themselves for the public approval by a diligent and ready self-examination. Mr. Neale visualized for them, as it had never been made visual before, the importance of the work they were doing. He saw clearly just why the tonnage did not reach in full the possibilities which labor supply, opened mines and railroad-car service justified the nation in expecting.

From this man the coal miner and the coal operator got justice, judgment and sympathy. In a rough and ready world neither of the parties get enough of these things. Blame and recrimination are bandied around all too freely. For a while we were allowed each to view himself sanely and honestly, neither extenuating faults nor painting them blacker than they really were nor yet creating them when they did not exist.

With one bound, production and good-will advanced, especially in those places where Neale made his principal appeal. The nation owes him its thanks. He certainly served truly and well, and happy indeed is he who is honored by the opportunity to perform for the nation such a signal service as has been his.

Peace and Waste Are Not Synonymous

THE Hun has been defeated. The war, so far as active hostilities are concerned, is over. The chief purpose for which this country unsheathed the sword a year and a half ago has been accomplished. We rejoice in the belief that the world has been made safe for democracy. It must now be kept secure.

Aside from the main issue at stake—which has been settled by force in France—one of the greatest benefits derived from the war has been the lessons learned in conservation. Americans have learned that certain economies could be made without serious inconvenience. The tremendous sales of liberty bonds and of thrift stamps furnish striking illustrations of what the country as a whole has been able to do in a financial way. But many savings have been made in the shape of fuel and materials that have been quite as important to the country as the huge sums received by the Government.

The world is now entering upon a period of reconstruction in many respects quite as hazardous and crucial as the era of blood through which we have just passed. The present is no time to relax the reins of frugality and thrift, or to abondon the practices that have made victory swift and sure.

Perhaps in no resource have the savings effected in the past few months been more important than in coal. Consistent conservation has long been urged and encouraged by the United States Fuel Administration and other agencies. Some of the results obtained have been highly gratifying. Unfortunately, however, the benefits derived have not received the publicity that their importance warrants.

At the suggestion of the Fuel Administration, therefore, *Coal Age* extends an invitation to its readers to contribute articles or letters setting forth specific cases of where conservation measures adopted have borne fruit. Such articles should be illustrated if possible and should cover among other things the following three important points: What was done; how was it done; what results were obtained.

No man should "hide his light under a bushel." The needs of the country are now, and will be, as great during the next few months as at any time in the recent past. If you have been successful in your attempts at fuel conservation let your experiences be known that others may be encouraged to follow your example and save coal against the needs of humanity.

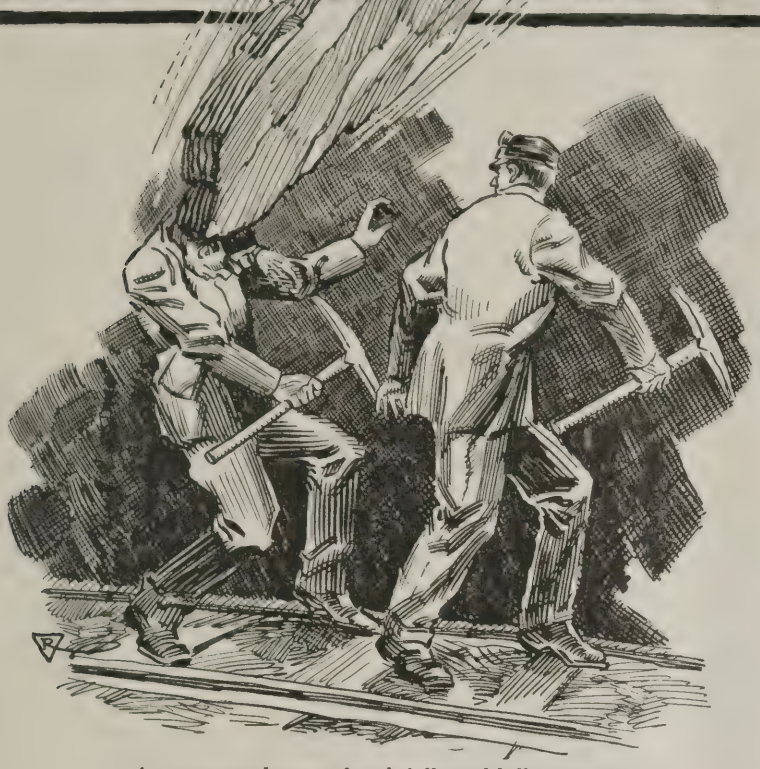
What Coal Are You Burning?

THE president says to the manager: "Of course we will burn our bugdust under our boilers." The manager assents, and the order goes forth: "Dump the bugdust cars over the boiler chute." The order is obeyed. Presently a cutter in 20th left complains he has no power for cutting. The motorman in the 6th face reports that he cannot make the hill beyond the swag at 15th right because he hasn't the "juice."

The foreman comes out in hot haste and interviews the engineer in the power house. He blames the boiler-room men, but says they haven't a chance to keep up a brisk fire and a boiler full of high-pressure steam on the bugdust supplied them. Then the foreman changes the orders and says the bugdust must be sweetened with a few cars of lumpy coal, and soon the boiler house gets the cream of the coal and the bugdust goes to market.

Of course, no one reports that the bugdust is no longer being used. It is likely that the president of the company never finds out that fact. The manager makes a few feeble protests, but he finally gives the assent of silence and looks at the coal pile with a blind eye, except on the day when the president is expected. Then he passes a tip to the foreman, and bugdust goes to the furnace, and the mine slacks hopelessly in consequence all along the line.

The only way to prevent this is to put in mechanical stokers that will burn nothing but small coal and will burn it efficiently, while keeping up a full head of steam. Your orders must then be obeyed, for the mechanical stoker doesn't know how to burn anything but the small sizes. Your furnace man doesn't make any objection against his work, for the bugdust is fed by machinery. You save money and get your own way—which is worth something. Nobody will ever get his own way who, with the modern fireman and without mechanical stokers, tries to utilize his bugdust in the generation of steam.



Reëstablishment or Reconstruction?

MUCH water has passed over the dam since the war was declared back in 1914. It is gone. We can no longer impound it. Wages have risen, costs also have gone up. These matters cannot well be corrected. The change has done little good to the workingman, but he would not stand to have his wages reduced even nominally. So let the wages alone, and values also.

We have, however, to put back our war workers and our armies into peace industries. But in so far as changes are made, let them be in the nature of reëstablishment rather than reconstruction. Now is no time to recast the social fabric. The problems involved in maintaining it are severe enough. Let us have, if you will, a new spirit; but let us not attempt by law to create a new order.

FALLS ON ROADWAYS & TRAVELLING WAYS

Safety letter of a large Coal Company to its men

An unreported piece of rock falls and kills its man

THIS summer two miners were walking out of the mine to the place where they get on the man trip. One stopped, the other passed on, and at almost that instant a large piece of slate fell, killing one instantly.

Probably a number of men had passed that piece of slate that day. It is hardly possible that no one noted that it was becoming dangerous, but the big thing is that no one felt that it was his particular duty to give it special attention or even to send the word of warning that might have saved a man's life.

Never mind the fire, no one will pay me for reporting it

THE maintenance of traveling ways in a safe condition is primarily the duty of the mine foreman. We all know that he will spare no expense in securing safety when he knows of an immediate danger, but he cannot be at all parts of the mine at all times. A dangerous condition may arise in but a few minutes and each man should feel that it is his duty to give warning as soon as danger is perceived.

Safety work is like many other things in life which are above payment—done for humanity's sake and because we expect as payment that the other man will do likewise. Would you think of waiting till someone gave you a $10 bill before waking up your neighbor at night if you saw his house on fire? Yet how often will you scoot by a dangerous place and expect the next man to be equally alert and see it.

They scoot by and let the rock fall on the other fellow

THIS is where we who work in the mines fail in reciprocative safety, the most important of all safety work. Don't be a safety slacker. We must train and educate ourselves to feel that the other man deserves the benefit of our knowledge whenever we see an immediate danger and that we must not fail to take the few extra steps to warn our fellow employees or at least to get the proper information to those who will either warn them for us or remove the danger.

We all use the manways, we all take a like chance from any danger that exists in them, consequently we should make their safety a coöperative affair. Let us all get together and take a part in keeping them safe so that another accident as above described will be impossible.

DISCUSSION BY READERS

Accounting of Materials

Letter No. 2—Referring to the excellent letter of J. Kenvin, on the accounting of mine supplies and materials, *Coal Age*, Oct. 17, p. 754, which possesses much merit and cannot fail to be of interest to all, allow me to present a simple form of cost-sheet that I have found useful, in my eight years of service in the offices of coal companies. They appeal to me as being the simplest and best of the various forms I have seen in use.

It is my experience that many coal companies do not attempt to keep an accurate cost-sheet, because they are unwilling to go to the expense of employing a man capable of that work, while other companies fail to realize its importance and are confused by the seeming complications and endless chain of forms that they believe are necessary for the purpose.

The cost-sheet submitted here is a simple affair, causing no extra expenditure for numberless forms and instructions, which fact has been much appreciated by all operators who have used it. The cost-sheet is so constructed that anyone around the office can figure it out in an hour's time. The form submitted here gives the departments generally used around a drift-mouth mine, but blank spaces are left so that any one can add what extra accounts they may desire.

All that is necessary to obtain at a glance the cost of labor is to arrange the foremen's time book so as to show a separate division for each department of the work, giving to each division as many lines as required for the number of men employed in the department represented.

PORTION OF MINE FOREMAN'S TIMEBOOK, OCTOBER 15-31, SHOWING METHOD OF DISTRIBUTING TIME

Shown above is a sample page torn from a mine foreman's timebook for the last half of the month of October, 1918. It shows the number of hours worked by each man, in the several departments that appear on this page, and the total for each man, in each department, with his rate and amount due him.

In order to keep an accurate account of the cost of labor in each department, the number of hours a man works in each must be charged in its proper place. For example, on the page here shown, John Smith worked only 6 hr. on the motor, Oct. 25, when the mine shut down for lack of railroad cars. He then worked 2 hr. repairing track. Similar distribution must always be made when men are shifted about in the mine. The total cost of labor is summed up, as shown, for each department.

The reason for calling special attention to the need of proper distribution of time is that so many coal companies are charging the total time worked by employees to the class of work under which they are listed as their regular job. Many operations, for instance, charge the labor of oiling the mine cars, under the head of tipple labor. As a consequence, if they were asked to state the cost of operating their mine cars, the amount would not include the oiler's salary.

Importance of Accurate Time Distribution

But, during these strenuous times when every operator is striving to increase his production at the least possible cost, it is very important to know exactly what each department is doing. Many scientific methods are being offered, many of which will not only help to increase the output but enable an operator to show a satisfactory saving in the cost of production. How will an operator who merely guesses at his cost, by using estimates, know when an "honest to goodness" saving proposition is made to him?

Where an operator realizes the need of accurate accounting and adopts such a cost-sheet as I have suggested, every foreman should be made to keep his timebook so as to show the hours each man works in each department for which a separate account is kept, and sign the same, so that it can be accepted as correct by the payroll clerk.

No corrections will be made on payday; but if any time is due a man he should be given credit on the payroll then open, and the amount charged to the proper department. Pick and machine coal comes in on the coal-sheet every day so that one can easily prove the correct tonnage for each class of coal and the amount paid for the mining in each section of the mine.

Material to be used in and around the mines should be inventoried as received and placed in the supply house, which should be kept under lock and key, and a competent and reliable man placed in charge and held responsible for all material. Every foreman should understand that he must send a written order for such material as he may need. The order must show what material is wanted and to what department it is to be charged, as for example:

STOREHOUSE KEEPER:
Please deliver to bearer:
2 Trolley poles (6 ft.);
1 Trolley wheel, No. 120.
Charge to Electric Haulage.
100 Morgan & Gardner mining machine bits.
Charge to Mining Machines.
(Signed) Bill Jones, Mine Foreman.

Each order when filled should be taken and priced with the average cost of the material, as shown by the invoices. Freight and express should be added to all invoices, unless they are bought delivered. This order should then be filed until the close of that half-month, when a sheet of paper with all the departments shown should be taken and the amounts shown on the orders charged under each head.

I believe this is as simple a system as can be devised and will give an accurate cost of labor and material for each department. A simple perpetual inventory can be maintained as a check against material bought, on hand and used.

The overhead charges shown in the following lines must be left to the operators to distribute as they think best.

OVERHEAD CHARGES

Superintendent			
Office			
Insurance			
Taxes			
Workman's compensation			
Royalty			
Sinking fund			
Proportion of main office expense			
Total			

The yearly salary of the superintendent is generally divided up between the mines and commissary and a certain percentage charged to each department. Insurance and taxes paid each year will be charged off each month or semi-monthly in equal amounts. For instance, $2400 paid for insurance in a year, would mean $200 a month or $100 for a half month. Taxes are to be handled the same way. An average charge for main-office expense must be distributed in like manner.

Workman's compensation is generally carried by every mine these days. The amount actually paid the compensation commission should be entered, less the amount collected from the employees. Where royalty is paid, the amount per ton can be applied against the tonnage produced. Royalty is generally paid on a tonnage basis of 2240 lb. Hence, an output of, say, 10,000 tons of 2000 lb. would equal (10,000 × 2000) ÷ 2240 = 8928.5 gross tons, subject to royalty. A sinking fund is an amount, per ton, charged off to take care of improvements, etc., and is generally assumed as 5c. per ton. Thus, 10,000 tons @ 0.05 = $500 charge to sinking fund.

I have made up a card memorandum of accounts, which I think will take care of all the departments shown. I may have omitted some accounts that should be shown under some of the departments. If so, it will be easy to add whatever is wished to these accounts.

COST-SHEET

The Blank Coal Company, Montgomery, Ala.
For Period Ending Oct. 15 to 31, 1918

Labor	Amount	Cost per Ton	Comparative Cost Last Half
Pick coal

The following is a copy of a card index or memorandum for reference, showing classification of items of labor and material in common use.

CARD ACCOUNTS

M-1 Pick Coal
(a) Labor paid for pick mining

M-2 Machine Coal
(a) Labor paid for machine mining

M-3 Contract Coal
(a) Labor paid men who are working for contractor
(b) Amount paid contractor after deducting his expenses as shown above

M-4 Machine Cutting (Labor)
(a) Amount paid machine runners for cutting coal

M-5 Yardage (Labor)
(a) Scale, rates for slate
(b) Cleaning up slate falls and moving gob

M-6 Inside Labor
(a) Firebosses
(b) Mine foremen and assistants

M-7 Track (Labor)
(a) Foreman of track
(b) Tracklayers
(c) Helpers

M-8 Mule Haulage (Labor)
(a) Boss driver
(b) Drivers
(c) Stable boss

M-9 Electric Haulage (Labor)
(a) Motormen
(b) Brakemen
(c) Wiremen and bonding

M-10 Storage Battery Loco. (Labor)
(a) Motor runner
(b) Brakeman
(c) Labor for charging

M-11 Water and Ventilation (Labor)
(a) Trappers
(b) Brattice
(c) Pumpers
(d) Water bailed in cars

M-12 Timbering (Labor)
(a) Labor for timbering

M-13 Power (Labor)
(a) Engineers
(b) Firemen
(c) Extra labor for repair
(d) Electricians' salary

M-14 Electricians (Labor)
(a) Labor provided it is not distributed to work actually done

M-15 Tipple (Labor)
(a) Tipple workman
(b) Weighmaster
(c) Car droppers
(d) Pickers
(e) Inspectors and car rounders

M-16 General Outside (Labor)
(a) Timbermen getting mine timber
(b) Saw mill operators who saw timber for the mines
(c) General repairs on the outside pertaining to the mines
(d) Teamsters

M-17 Blacksmith (Labor)
(a) Labor repairing miners' tools
(b) Labor shoeing teams

M-18 Mine Car Repairs or Replacements
(a) Carpenters
(b) Helpers
(c) Blacksmiths
(d) Labor of oilers or greasers

M-19 Motor Repairs (Labor)
(a) Electrician and other labor

M-20 Mining Machine Repairs (Labor)
(a) Labor electricians and other labor

M-21 Drumhouse and Incline
(a) Drum runners and helpers
(b) Couplers
(c) Labor repairing incline, cable, etc.

M-22 Monthly Men Salaries
(a) Any monthly man's salary who is not charged to any particular department can be charged to this account

MATERIALS

M-30 Yardage
(a) Any dynamite, powder fuse, etc., used in the mines for which no charge is made

M-31 Track
(a) Spikes, nails, ties, rails, switches, plates and bolts
M-32 Mule Haulage
(a) Mule shoes, nails, etc.
(b) Horses and mules replaced
(c) Harness
M-33 Electric Haulage
(a) Repairs used
(b) Waste, oil, etc.
(c) Trolley wire, bonds, hangers, etc.
M-34 Storage-Battery Locomotive
(a) Repairs used
(b) Power for changing batteries
(c) Waste, oil, etc.
M-35 Water and Ventilation
(a) Brattice cloth
(b) Pumps installed and repairs to same
(c) Timber, cement, brick, etc.
M-36 Tipple
(a) Repairs
(b) Installation of new machinery
M-37 Mine Timber
(a) Post and other timber used in timbering
M-38 Power
(a) Waste, oil and other supplies
(b) Installation of new machinery
(c) Coal used for boilers (this account should not be added until you have found your actual cost per ton, including supplies, labor and overhead)
M-39 Mining Machine Repairs
(a) Bits, jacks and other repairs
(b) New machinery
M-40 Mine Car Repairs
(a) Timber, wheels, axles, bearings, nails, bolts and other supplies
(b) Lubrications
M-41 General Outside
(a) Material used for general repairs pertaining to the mines (not house repairs)
M-42 Stable
(a) Feed used in feeding teams
M-43 Drumhouse and Incline
(a) Cables, switches, rail, ties, spikes, etc., used for repairing
M-44 Office Supplies

OVERHEAD CHARGES

M-48 Superintendents
(a) Proportion of superintendent's salary (part of which should be charged to commissary)
M-49 Office
(a) Salaries of office men (not including payroll clerk, which should be charged to commissary with other help in that department)
M-50 Insurance
(a) Proportion of yearly premium
M-51 Taxes
(a) Proportion of yearly tax
M-52 Workmen's Compensation
(a) Amount paid each month less the amount collected from men
M-54 Royalty
(a) Amount paid per ton as (10,000 tons @ $0.08 = $800 premium paid)
M-55 Sinking Fund
(a) So much a ton charged off each month to take care of improvements
M-56 Main Office Expense
(a) Get the main office to give you an amount which will represent a fair average of your department's expense each month

I sincerely hope this cost-sheet will be found suitable by a good number of practical operators, and particularly would I like to see it discussed in *Coal Age*.

———, W. Va. A. T. LAMENT.

Hauling Capacity of Locomotives

Letter No. 1—The inquiry of a West Virginia operator regarding the hauling capacity of a storage battery locomotive is an interesting one, and the reply given, *Coal Age*, Oct. 3, p. 660, is all that could be expected from the data given. However, what impresses me as being the most important, in this case, is the possible effect of the substitution of flexible roller-bearing wheels for the plain-bearing wheels with which the mine cars are said to have been equipped.

It is unfortunate, in my opinion, that this operator listened to the advice of his friend and gave up his original idea of replacing the old plain-bearing wheels with those of the flexible roller-bearing type, as he said he contemplated doing. It is my belief that this change of bearings would have solved the difficulty.

Plain-Bearing Cars Cause Excessive Drain on Batteries

It is stated in this inquiry that the batteries of the locomotive gave out after about six hours' work. Now, when one realizes the great saving of power made possible by the substitution of flexible roller bearings for plain bearings, it is reasonable to suppose that such a change would have gone far toward assisting the batteries to hold out during an entire shift.

Practical tests have shown that it requires about two and one-half times as much power to start a trip of plain-bearing mine cars as it does to start the same trip when the cars are equipped with flexible roller bearings. It is clear that excessive drains on the batteries are caused by the frequent heavy overloads that occur where plain-bearing cars are used; and this tax or drain shortens the working day of a storage-battery locomotive. Such being the case, it follows that the plain-bearing wheel is really a governing factor in determining the hauling capacity of a battery locomotive.

Flexible Roller Bearings Effect a Saving of Fifty Per Cent. of Power

Allow me to refer briefly to the results of the reliable tests that were made by the manufacturers of flexible roller bearings for mine car wheels. The tests were made in coöperation with a number of coal-mining officials. In one of the tests, it was shown that the drawbar pull of cars equipped with plain-bearing wheels was 24.3 lb. per ton of load hauled on a horizontal track, while that of cars equipped with flexible roller bearings was only 12.8 lb. per ton of load hauled. A similar test made at another time and in another place, before a large assemblage of mining men, gave the drawbar pull, for the plain-bearing cars tested, as 32 lb. per ton of load hauled on a horizontal track, while that for flexible roller bearings, under the same conditions, was 13 lb. per ton of load hauled.

In the first of the tests mentioned, the saving of power was 47.3 per cent., while in the second test it was 59.4 per cent. For all practical purposes, therefore, it can be assumed that the saving of power effected by the use of flexible roller-bearing, in place of plain-bearing wheels, on mine cars hauled on level track, will range somewhat above 50 per cent.

It has been my custom, in comparing these two types of bearings, for the purpose of showing the saving of power by the use of the improved type, to take 28 lb., per ton of load hauled, as the track resistance for plain bearings, and 12.9 lb., per ton of load hauled, as the average for flexible roller bearings, which makes the saving in power practically 54 per cent.

It goes without saying that the actual saving in power would much exceed this average, in a large majority of cases, in practice, as the tests made at the mines on the plain-bearing cars furnished by the companies using them cannot be assumed to have been made under the worst conditions. The cars selected were probably above the average of those in use.

Dynamometer Readings Carefully Checked

In each of the tests mentioned the readings of the dynamometer car and the calculations were checked by the mechanical engineer of the coal company, or other reliable and disinterested person, and can be accepted as being truly representative and reliable. The same dynamometer car is now in the service of the government and its accuracy is undisputed.

One fact that is worthy of consideration is the constancy of drawbar pull, per ton of load hauled, when the cars are equipped with flexible bearings. Owing to the care exercised in the manufacture of these bearings, little, if any, wear takes place for a long period of time. Only recently, I heard a man who is in charge of a mine where the cars are equipped with flexible bearings, say that scarcely any wear could be observed on the axles or bearings that had then been in operation for about ten years.

In the same connection, the statement of J. J. Bumpus, of Sovereign, W. Va., which recently appeared in *Coal Age* [Vol. 13, p. 844] describing the work performed by a 5½-ton storage-battery locomotive, is worthy of note. This machine, it was stated, operated one year on a 3500-ft. haul, with a 3 per cent. grade against the loads. and hauled 125 loaded cars weighing 4 tons each, in a 9-hr. shift, the cars being equipped with roller bearings.

The same locomotive was then used six months longer for gathering cars at the face, before the life of the 48 lead-battery cells expired. During this 18 months' service, the locomotive had taken the place of four mules and three drivers, and was operated continuously, with a total cost for repairs of $86.45, which does not include the replacing of exhausted battery cells with new ones.

In closing, let me draw attention to the fact that the last instance cited bears a close analogy to the case mentioned in the inquiry to which I have referred. In each case, a storage-battery locomotive is described as operating on a 3 per cent. grade, the statement in the inquiry being that the grade did not exceed 3 per cent. This confirms me in the opinion that the substitution of flexible bearings for the plain bearings in use would have proved equally successful in the instance mentioned in the inquiry, as in the case cited by Mr. Bumpus.

For the sake of argument, allowing the 28 lb. per ton, previously mentioned for track resistance, and 60 lb. for a 3 per cent. grade resistance, making a total of 88 lb. per ton of load hauled, with plain-bearing cars, as compared with 12.9 lb. track resistance and 60 lb. grade resistance, or 72.9 lb. per ton for flexible roller-bearing cars, the difference between the two types then being $88 - 72.9 = 15.1$ lb., per ton of load hauled, the saving in power is $(15.1 \div 88) \times 100 = 17.16$ per cent. It is important to remember that the ease with which flexible roller-bearing cars are hauled up a grade makes them seem to almost "float" over the high spots in the road, and I can recommend this type of equipment without hesitation. HOWARD K. PORTER.

New York City.

Mining Equipment

Letter No. 9—In reading the many interesting letters on mining equipment that have appeared in *Coal Age* and in answer to the suggestion so often made that coal operators should *pass on* their ideas and not hold back what they have found useful in their own practice, it occurred to me that one little device that has been in use in our mines for some time past might be of interest and help to others.

We are using a No. 3 electric mine locomotive to haul our cars. There are several steep grades on the haulage roads; and many, who have worked under similar conditions, will know what it is to set sprags in 15 or 20 cars and run the risk of having one's fingers caught in the wheels. Then, when the trip has landed in a swag, one must crawl over cars, climb couplings and squeeze between other cars and close ribs, in order to take out the sprags and enable the trip to be hauled up the next grade.

In order to overcome these difficulties, we set to work some time ago and devised what might be called a "drag slide," which was applied to the last car of the trip when descending a steep grade. This drag slide was a simple affair, costing little, and proving a great success. It takes but a few moments to put on or take off, and is a great improvement over the old method of spragging the cars.

The drag slide is made of two angle irons fitted to slide on the rails. They are long enough to turn up at the front end in the same manner as tipple horns on a dump, and reach back under both wheels. The affair is substantially made and when in use forms a sled on which the rear car of a trip rides. To apply the drag the rear car is uncoupled and pushed back, the drag slide placed on the rails and the car shoved over it and again coupled. A chain can be used to hold the slide in position if this is necessary.

We have found the use of this drag to be of great benefit. It serves to hold the trip straight and steady, which has the effect of reducing the jerks that always occur when a locomotive starts a trip of cars and the couplings take up the play. This reduces the strain both on the cars and on the locomotive. Another benefit is the great saving of car wheels, which are rapidly worn when sprags are used. I have submitted the description of this little device for what it is worth, hoping it may prove of as much value to some others as it has to us.

Crawford, Tenn. W. T. HALE.

Estimating Percentage of Grade

Letter No. 1—Having read carefully the inquiry of "Mining Engineer," *Coal Age*, Oct. 17, p. 756, in regard to the best method to use in calculating the percentage of grade, and having had considerable experience in this kind of work, in the employ of some of the largest coal companies in this district, let me say that I have always used and been instructed to use the method where the percentage of grade is based on the horizontal distance. I agree with the suggestion that this is a good subject for discussion, because without a thorough understanding of the method used there would be many errors in reading mine maps. My reason for thinking that the horizontal basis is the best method to use lies in the fact that, as most mine maps are made on the horizontal scale, it makes it much easier to determine the grade betwen any two points on the map. All that is then required to find the grade between two points is to divide the difference in elevation between those points by the distance taken from the map and the result is the required percentage of grade.

MAKES THE WORK MUCH EASIER

Compare, for instance, a case where the other method is used and the per cent. of grade is based on the pitch distance, with one where it is based on the horizontal distance. In studying the mine map, in my opinion, it would be easier for a mine foreman to make a mistake in calculating a grade based on pitch measurement.

In such a case, it would be necessary to first calculate the pitch distance by dividing the distance on the map by the cosine of the angle of inclination. It is right there that one has a possible chance for an error, either in his mathematics or by taking the wrong cosine from the table.

In the former method, in order to calculate the grade, one does not need to use any distances that he himself must determine, because the required distance is given on the mine map and all that he has to do is to make a simple division.

In closing, permit me to say that I think the better method of the two is that where the per cent. of grade is based on the horizonal distance. That is the only method that I have ever used and I believe it is the method where the least chance for error exists.

Plymouth, Penn. JOSEPH R. THOMAS.

Iron vs. Wood Mine Cars

Letter No. 3—Regarding the question of which is the better, iron or wood cars, for use under all conditions in mines, it is necessary to consider carefully the power employed for hauling. What would be suitable for motor haulage would not necessarily be best to employ in animal haulage, as the strength of the horse or mule must be taken into account. Likewise, in rope haulage, we must have regard to the strength of the rope before deciding in favor of adopting iron cars.

Where animal haulage is employed in a mine, the use of iron cars is almost out of the question, owing to the greater weight of an iron car for the same capacity. Assume, for instance, that a horse will haul four wood cars carrying 2 tons of coal apiece. If the cars weigh 1¼ tons, the total weight hauled will be $4(1\frac{1}{4} + 2) = 13$ tons. A good horse or mule working under favorable conditions will be able to handle such a trip and stand the strain for an 8-hr. day and, after a night's rest, be in shape to do the same work the following day.

IRON CARS A HINDRANCE IN ANIMAL HAULAGE

Now, suppose iron cars weighing, say 1½ tons each, and having the same capacity are substituted for the wood cars. A four-car trip, in this case, would weigh $4(1\frac{1}{2} + 2) = 14$ tons. A horse pulling this load would hardly hold out to the end of the shift and would be so fagged out and exhausted that the work would soon tell on him and shorten his period of usefulness.

Again, with the same running gear, these two types of cars cannot be hauled with the same ease. There is a give to a wood car that makes it easier to haul but an iron car is rigid and does not run as readily on the same track. This fact can only be thoroughly appreciated by those who have had experience in hauling both kinds of cars.

Owing to these hindrances, while a good horse can make, say 12 trips a day, hauling four wood cars in a trip, and stand up to the work, if iron cars of the same capacity are used instead of wood it will be necessary to cut the trips down to three cars each, and that would reduce the output of the mine one-fourth. Estimating on 12 four-car trips a day, with wood cars having a capacity of 2 tons each, gives an output of 96 tons. The use of iron cars, in that case, hauling 3 car trips, would necessitate a loss of 24 tons. This fact alone would seem to be sufficient to bar the use of iron cars where animal power is employed for hauling.

With motor haulage, the case is somewhat different. However, even here, the rigidity of iron cars throws a greater strain on the locomotive, and the necessary bumping and jerking, in starting trips, causes more injury to the cars than where lighter cars are in use. Broken axles are more frequent on iron cars than on wood ones, because of the rigidity of the former. It is, no doubt, true that wood cars are more easily injured and broken in a wreck than iron ones; but they are the simplest and cheapest to repair, at any ordinary mine shop. Suppose, in case of a wreck, 10 cars are so badly damaged that they cannot be used until they are repaired. If these are wood cars, they can probably be put in shape in one or two days and sent back into the mines. On the other hand, iron cars in a similar wreck would be battered in such a manner that it would require several days or weeks to put them in condition for use again. In some cases, it will cost more to straighten out an iron car than to build a new one and such cars must be thrown aside, unless the shop is properly equipped to handle the work.

Much that has been said with reference to the use of iron cars in animal haulage will apply, in somewhat less degree, to rope haulage, whatever system is employed, as the rope will be overtaxed in most cases and may break when least expected and cause a serious wreck. However, this can be largely avoided by the use of heavier and stronger rope when hauling trips of iron cars.

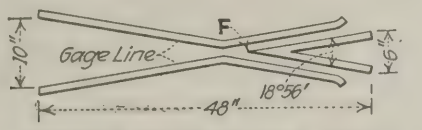
IRON CARS CAN BE BUILT MUCH LIGHTER AND MADE MORE SERVICEABLE

It may seem, from the foregoing, that I am an advocate of the sole use of wood cars in mine hauling; but this is not the case, provided a suitable kind of iron car is brought into service. My experience with iron mine cars is that they are built much heavier than there is any need. It is my belief that an iron car having a capacity of 2 tons should not exceed half this weight when empty. That is to say, the weight of the empty car should not be greater than one-third of its weight when loaded.

In the manufacture of iron cars, I am satisfied that the thickness of the steel shell or body can be less than is ordinarily employed, and that the frame can be constructed of ⅜ × 2-in. angle or channel iron, while the axles need not be more than 2½ in. Such a car would not require more than the ordinary size and weight of wheels. The bed of the wagon should be rounded to a half circle.

In my opinion, the repair of this style of iron car would not require much more in the way of shop equipment than is necessary for the repair of wood cars. The repair of iron cars, particularly in wet mines, it seems to me, calls for a well-defined system. The requirements must be closely studied with a view to securing the greatest economy in this work.

My plan would be to number each car and make it a rule that 10 cars should be sent out every Saturday and given a good coat of hot coal tar reduced to a thin liquid. This should be applied inside and out, alike. The nuts of all bolts should be on the inside of the car, so that none but mushroom heads would appear on the outside. The corners of the car should all be rounded so as to reduce the tendency of the iron to catch anything in its way. Where such a car can be furnished, I believe it would prove more serviceable than a wood car when power is employed for hauling.



Perryopolis, Penn. R. W. LIGHTBURN.

INQUIRIES OF GENERAL INTEREST

Mine-Switch Calculations

I have been a constant reader of *Coal Age* for some time past and have noticed many articles and questions asked in its columns, regarding tracklaying, turnouts and switches in mines. These have always been of interest to me, and I have frequently made use of the information thus gained, in my work in the mines.

Recently, we have had some argument on the lengths of lead rails and latches required for a frog laid in a turn-out, near the shaft bottom. In order to make the case clear, I have drawn the inclosed sketch of this frog which, by my way of figuring, is a No. 3 frog. As shown in the sketch, the frog is 48 in. long, out to out,

COMMON FORM OF RAIL FROG

and has a spread of 10 in. at one end and 6 in. at the other end, the spread being measured between the gage lines of the rails. As I understand it, the "lead rail" is the curved rail running from the point of frog, marked *F* in the sketch, to the point of switch, which is the point of the latch in the main road.

The track gage, in our mine, is 42 in., and the length of the lead rail, as measured, is 21 ft. 9 in. I want to ask if this is the correct length for this rail. I have calculated the frog angle as 18° 54′. My method of calculating the number of a frog is to divide the length of the frog, out to out, by the sum of the spread of the rails at each end of the frog, which gives for the frog number, in this case, $48 \div (6 + 10) = 3$. We shall watch with interest for the reply, as we are anxious to know what is right. TRACKLAYER.

————, Ill.

The method of finding the number of a frog, as described by this correspondent, is correct. The frog is a No. 3, rail frog. The length of lead rail, or the curved rail extending from the point of frog *F*, to the point of switch or the point of the latches in the main road, is calculated, as has been frequently explained in *Coal Age*, by multiplying twice the track gage, in feet, by the number of the frog. Thus, for a track gage of 42 in. or $3\frac{1}{2}$ ft., the length of lead rail is

$$l = 2gn = 2 \times 3\tfrac{1}{2} \times 3 = 21 \text{ ft.}$$

The length of the latch required will depend on what clearance is desired between the hinge of the latch and the gage line of the main rail. Thus, expressing all dimensions in feet, the length of the latch is equal to the square root of the product of twice the radius of the curve and the desired clearance. The length of radius (R) of curvature of the lead rail is found by multiplying the length (l) of the rail by the frog number (n), which gives, in this case, $R = ln = 21 \times 3 = 63$ ft. Finally, calling the length of the latch x, the radius of the curve R, and the desired clearance between the latch and the main rail d, we have for a clearance of 3 in. or $\frac{1}{4}$ ft., in this case,

$$x = \sqrt{2Rd} = \sqrt{2 \times 63 \times \tfrac{1}{4}} = 5.61 \text{ ft.}$$

For a clearance of 4 in. or $\frac{1}{3}$ ft., the length of latch is

$$x = \sqrt{2 \times 63 \times \tfrac{1}{3}} \quad 6.48 \text{ ft.}$$

Portable Coal Loaders

I am writing to ask for any information that *Coal Age* can give me, in regard to a portable machine for loading coal at the working face. We are mining a 9-ft. seam of coal and I am desirous of installing a machine that will load this coal to the best advantage, with regard to economy and ease of handling. The different types of conveyor belts that I have been considering do not appeal to me as suitable for handling and loading the coal, in our case. In one instance, the belt was only 12 in. wide, which is much too small for our purpose. Any suggestions that *Coal Age* can offer that will assist in solving our problem will be greatly appreciated.

Rugby, Colo. OPERATOR.

From the statement in this inquiry there is some doubt as to the kind of loading equipment desired by the correspondent. There are a number of chain, belt and scraper conveyors now on the market. These are mostly designed for transporting the coal along the working face to the roadhead where it is dumped or loaded into the mine cars to be hauled out of the mine. The different types will be found advertised by their manufacturers, in the advertising columns of *Coal Age*, each type having its peculiar advantage and adaptation to varying conditions.

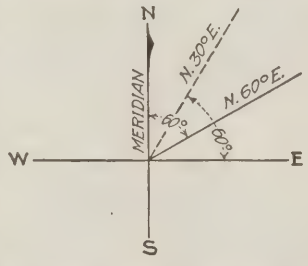
As a rule, all kinds of face conveyors are designed and adapted for use in the working of thin seams of coal where the mine cars cannot be taken along the face to be loaded. Such conveyors are particularly adapted to longwall work, where the roadheads are often 100 yd. apart, affording a good opportunity for the operation of the conveyor.

In a 9-ft. seam of coal, as in this instance, it would seem that a coal loader of the Myers-Whaley type, which was described in *Coal Age*, Oct. 10, p. 711, would be well adapted to the work. This machine is both a shoveler and a loader and has been found to work very successfully, shoveling the coal from the bottom, elevating, transporting and dumping it into the mine car at hand. The machine is portable.

Another light and portable coal loader is that manufactured by the Jeffrey Manufacturing Co., which differs from the one just mentioned by requiring the coal to be shoveled into the conveyor by which it is transported and dumped into the mine cars standing close at hand. Any of these types of loaders are recommended as giving good results under varying conditions.

EXAMINATION QUESTIONS

Miscellaneous Questions



(*Answered by Request*)

Ques.—Under what conditions is it safe for men to enter return airways contaminated by gases emanating from a mine fire?

Ans.—No one should be permitted to enter a return airway that is filled with gases generated by a mine fire, unless he is protected by an approved form of breathing apparatus. There is always a large amount of carbon monoxide produced by the fire, and this gas is very poisonous and may produce instant death if present in sufficient proportion in the air current.

Ques.—What is the difference between north 60 deg. east and 60 deg. north of east?

Ans.—As shown in the accompanying figure, a line having a bearing of N 60° E makes an angle of 60 deg. to the right of the meridian, facing in a northerly direction. On the other hand, the direction or bearing described as 60 deg. north of east would indicate that the line makes an angle of 60 deg. with a due east line, the angle lying on the north side of the line. In the figure, the bearing first named is indicated by the full line, while the dotted line represents the second bearing named. The true bearing of this second line should be expressed as N 30° E, instead of 60 deg. north of east.

ILLUSTRATING BEARINGS

Ques.—What should be the daily procedure of a mine foreman?

Ans.—The foreman in charge of a mine should be on hand at the shaft or slope bottom when the men are about to enter the mine for work. His first duty is to inspect the report of the fireboss or firebosses who have examined the mine that morning, and see that it is reported safe. The foreman must note what dangers have been found as stated in these reports, and give instructions to his men in regard to removing such dangers and making the places safe for work. The foreman should withhold the checks of any miners whose places are reported unsafe for work.

After starting the miners and instructing the company men in regard to their work, the foreman must give his attention to the hoisting of coal and the work of the drivers. In making his daily rounds, the foreman must see that the working places are properly ventilated and timbered. He must examine carefully the roof in each place and give the miners any needed instructions regarding their safety. The foreman must see that all roadways and air-courses are properly timbered and safe. He must also examine all abandoned and void places in the mines and see that they are free from accumulations of gas and other dangers.

In addition to these duties, the mine foreman must attend to the needed supplies of material and order whatever is necessary for the operation of the mine. At the close of the day the foreman must ascertain that all of the men have left the mine. The foreman is responsible for the mine being operated in compliance with the mine law. He must see that the rules and regulations of the mine are obeyed and discipline men guilty of any violations.

Ques.—What conditions would guide you in determining the size of pillars in mine workings?

Ans.—The conditions affecting the size of mine pillars are the following: The nature, character and depth of the overlying strata; the quality, thickness and inclination of the coal; the nature of the floor or underlying strata; the size of openings and method of working employed; the time that must elapse before the pillars are to be drawn; and the presence of water or gas in the seam or contiguous strata.

Ques.—State what, in your opinion, would be considered as a main door.

Ans.—A main door, in mine ventilation, is a door separating the main intake from the main return airway. Any door leading from the main intake airway into another airway or section of the mine is also rightly called a main door.

Ques.—How would you distinguish between a rupture of an artery or a vein, where the victim is bleeding profusely? What steps would you take to protect the life of the victim?

Ans.—The blood coming from a ruptured artery will have a bright-red color and issue in spurts or jets, corresponding to the throb of the heart. On the other hand, blood flowing from a vein will have a darker color and issue quietly without spurting. In the former case, expose the wound so as to locate the point of rupture and apply a bandage so as to press tightly on the artery, between the point of rupture and the heart. This will check the flow of blood from the wound and give opportunity for the blood to form a clot at the opening. In applying such a bandage, a tourniquet should be used to insure a sufficient pressure on the artery and check the flow of blood from the wound.

In the case of a ruptured vein, remove any tight wrapping that would prevent the free flow of blood back to the heart and apply a bandage directly over the wound, which will assist the formation of the clot of blood and stop the flow at that point. In any case of serious bleeding, send for a doctor at once.

Candidates are constantly asking *Coal Age* to answer the questions asked in their state examinations. Examining boards are requested, therefore, to forward to *Coal Age* copies of the examinations, as soon after the examinations are held as possible. This will prevent mistakes, which are often made by candidates sending incorrect questions with requests for answers.

COAL AND COKE NEWS

What Happened in October

[The bracketed figures in the text refer to pages in the present volume, and should the reader desire further information he can obtain it by reference to the pages indicated.]

Oct. 3—Meeting of Anthracite Conciliation Board with union men and representatives of the Fuel Administration is held at Washington, D. C., the purpose being to consider whether the need for labor in the anthracite region furnished sufficient reason for a readjustment of wage which would bring the rate paid more nearly in accord with that in effect in bituminous mines and munition factories. [703]—C. E. Persons appointed Director of Education of the Fuel Administration [699]—Special maximum price set for coal of Loony Creek Coal Co., in Harlan County, Kentucky [744].

Oct. 4—Special maximum price set for coal mined by Montevallo Mining Co., in Alabama [744].

Oct. 7—Gladstone and Michel mine workers in Calgary field, British Columbia, vote to return to work under provision, of Sept. 27, of Dominion Director of Coal Operations [748]—Plant of Pike Coal Co. near Petersburg, Ind., is destroyed by fire [760]—Special maximum price set for coal of Southern Ohio Coal Co., Starr Township, Hocking County, Ohio, and for coal of Alliance Coal Co., Colorado.

Oct. 8—Conference of mine workers and mine operators of the anthracite region with Fuel Administrator Garfield consider data telegraphed from mining field relative to wage rates.

Oct. 9—Conlon mines fall in and cause much damage at Plains in anthracite region of Pennsylvania.

Oct. 11—Attempt is made to burn the tipple of the Panama Coal Co., near Moundsville, W. Va. [800].

Oct. 12—Fourth Liberty Loan drive commences [654, 704, 750]—Announcement is made of the Anthracite Wage Agreement as proposed and accepted by the wage board but not yet made operative [701, 703, 705, 789]—Main office of Thomas Colliery Co.'s mine, operated by Madeira Hill Coal Co., burns down [800].

Oct. 13—Fourteen bodies are recovered from the north mine of the Franklin Coal and Coke Co., at Royalton, Ill., victims of the fatal explosion of Sept. 28 [714, 760].

Oct. 16—United States Fuel Administration authorizes an increase in the reserve stocks of coal held by all classes of consumers except Class 1 east of the Mississippi River.

Oct. 18—Announcement is made that the United States had offered to place at the disposal of the Dutch government 100,000 tons of coal monthly till the end of the war on condition that food be not sent to Germany [800, 827, 865].

Oct. 20—Miners worked in large numbers in an endeavor to maintain production in face of influenza epidemic.

Oct. 24—New agreement in Vancouver Island, B. C., with wages increased 75c. a day with a sliding scale to adjust wages to cost of living [868].

Oct. 25—W. D. Tyler appointed Acting Director of the Bureau of Prices, vice E. Q. Trowbridge, who resigns for army service.

Oct. 26—Dr. H. A. Garfield, United States Fuel Administrator, announces that "the Fuel Administration approaches the winter season well organized with stocks of coal on hand far in excess of the stocks of other years".—Trade paper editors leave United States for Great Britain as guests of the British Bureau of Information [921]—New maximum prices set for coal mined by certain corporations in Bell and Harlan counties, Kentucky, and Wise County, Virginia, are made by United States Fuel Administration.

Oct. 28—United States Fuel Administration closes 13 small mines producing dirty coal [865].

Oct. 31—New anthracite wage scale as forecast Oct. 12 is made operative by the United States Fuel Administration [789, 867].

Harrisburg, Penn.

Coal companies must pay for the care of injured miners sent to hospitals, according to a decision of Judge Woodward in the suit of the trustees of the State Hospital of the Middle Coal Fields against the Lehigh Valley Coal Co. The dispute was presented to the court in the form of a case stated, and Judge Woodward of Luzerne directs that judgment be entered in favor of the plaintiff for $1,166.68, for the board and treatment of certain injured patients, who were employed by the defendant company. The case decides a question raised under the Workmen's Compensation Act.

Before the compensation act there was no obligation on the part of the employer to furnish treatment to the injured employee. So that if the employee went to the State Hospital the contract for treatment was between the hospital and the employee, and the purpose of the act, the court states, was to relieve the injured employee from the burden of payment. Before the Workmen's Compensation Act, if the employer had sent his employee to the State Hospital there would have been nothing to prevent his becoming responsible for his treatment, if he so stipulated. The compensation act now stipulates for him that he will be responsible if he sends his employee for treatment.

The court further states, "If on the other hand the employer had absolutely refused to furnish treatment, or had not been consulted, and the employee being a mine worker had gone to the hospital on his own account, the plaintiffs could not collect, because there would have been no privity of contract between the plaintiff and the employer, but only between the plaintiff and the employee, whom they could not charge for service; and as the compensation act only requires the employer to reimburse the employee for what he has spent for service, there would be nothing for the employer to pay."

The court contends that the obligation to pay in this case does not arise from that part of the compensation act which specifically requires the defendant to pay something, because the payment referred to is made to the employee and not to the person and institution rendering the service; but it arises from the obligation to procure treatment which was not on the employer before, and when the treatment is furnished the law creates the obligation to pay. The act creates the privity of contract which did not exist before, and the common law creates the obligation to pay a quantum meruit up to the limitation fixed by the compensation act. The State Hospital act does not prohibit the receiving of compensation except from the injured mine worker.

Uniontown, Penn.

Signing of the armistice will have no immediate effect upon the regulation of the coal and coke industry in the Connellsville region other than increase the difficulties of fuel officials in preventing the rank and file of the workmen from relaxing their efforts. Operators generally are inclined to welcome government supervision until the industry had readjusted itself to a peace-time basis. With the passing of the war appeal, however, a problem is presenting in retaining maximum efficiency among the workers to maintain tonnage at the high peak required to meet present demands. Definite policy in that regard has not yet been formulated.

Another low level was touched in production for the week ended Nov. 9, figures issued by the fuel administration placing the output at 610,604 tons of coal, of which 416,767 tons was manufactured into 277,849 tons of coke and 193,837 tons was shipped to byproduct plants and other industries. The figures in the aggregate represent a drop from the previous week of 44,600 tons and a decrease of 138,784 tons from the high record of Oct. 12. Coke dropped 17,711 tons and coal 22,500 tons. General peace demonstrations and influenza, which has not disappeared by any means, is blamed for the continued drop.

Three days after the effectiveness of the Pennsylvania Railroad order discontinuing box-cars to team-track loaders, no orders have been placed at the division office here for open-top cars by that class of operators, leading to the assumption that the team-trackers, as a class, had carried out their threat to discontinue operations. There were 155 of those operators served by the Pennsylvania R. R. with a daily rating of 175 cars, making a daily average output of 4275 tons. With the reduced price of 75c. per ton for coal loaded in open-top cars, the team-trackers claim they can make no profit. In addition there has been a decided slump in that grade of coal and instances have been reported of sales below the Government price.

Dissolution of the J. V. Thompson creditors' committee, a body established two years ago to protect interests of unsecured creditors with claims of $13,000,000 against the former coal baron, is asked in a petition in equity filed in the Fayette County courts by a number of creditors. An accounting of their management of the estate is also asked.

Sweeping charges of inactivity by the committee are made to support the plea for its dissolution, the claim being made that Thompson has at all times dominated its policy. The fight for the control of the Thompson Connellsville Coke Co., which has been pending here for several months, is also referred to in the equity bill. The charge is made that the sale of securities pledged with the First-Second National Bank of Pittsburgh as collateral was made to J. H. Hillman, Jr., at an inequitable price. The transaction, which included 5750 shares of stock in the Thompson Connellsville company and other securities, the petition avers lost to the Thompson estate a sum "in excess of $300,000."

Birmingham, Ala.

Greatly increased coal production in Alabama and the Birmingham district is shown in the figures for the week ending Nov. 2, when the output amounted to 347,557 tons. Operators and miners are being urged to push their activities to the utmost, to obtain maximum production during the remainder of the year. The fact that the war seems to be about over will not slow up the developments now being pushed in the mining sections of the district. Notable among these are those of the Republic company at Palos, the Tennessee company at Getmore, in the Blue Creek region, and the Woodward Iron Co., near Dolomite. These mines are on a large scale and will produce upward of 20000 tons per day each when in full operation.

The transportation companies in the Birmingham district are moving equipment as quickly as possible and the tonnage being reported shows steady increase. The intra-district business is also picking up, as the passing of the influenza epidemic has brought about improvements in the outputs of coal mines, coke ovens, furnaces, steel plants, foundries, machine shops and other industrial plants.

The announcement during the past week that the Birmingham Southern R. R., a subsidiary of the Tennessee Coal, Iron and Railroad Co., was losing its identity as a common carrier means the elimination of switching charges, brings about the right to charge demurrage and does away with many complications that heretofore existed. When the transportation charges deal now with the Birmingham Southern R. R., they deal directly with the Tennessee Coal, Iron and Railroad Co.

Warrior River transportation plans are still being carried forward rapidly, and with a favorable report at Washington last week by Assistant Director General of Railroads Tomlinson, in charge of inland waterways, early operation of the full resources of the system is expected. Advices from Washington state that Director General McAdoo may journey to Alabama next month to inspect the Warrior and act on the recommendations of Mr. Tomlinson.

Charleston, W. Va.

Pronounced improvement in production was made possible in the Fairmont region during the week ending Nov. 9 through a well maintained car supply covering practically the entire week, the mines in the district being able to rely upon about 1400 cars a day. Delivery of empties to the mines was also more prompt, although on one day cars were late in being placed. With less sickness among the miners more men were available for work. In one or two places only were operations crippled by the prevalence of influenza.

Little progress was made at the beginning of November by the mines of the Tug River and Pocahontas regions in meeting the quota of 2,000,000 tons assigned to those mines by the Fuel Administration as their goal for November. As a matter of fact production had fallen off considerably, dropping from 464,000 two weeks ago to 412,000, a difference in weekly production of over 50,000 tons. Production loss for the week was 63,855 and of that total inability to secure sufficient man power cost 41,596 tons. Production officials express the opinion that influenza kept a good many miners away from the mines. Car shortage had little to do with the decreased output but mine disability cut down the amount produced to the extent of over 11,000 tons. There was also a reduction in the tonnage of coke production, the amount being slightly in excess of 48,000 tons.

Conditions following the influenza epidemic in the New River field have made it difficult to command the full strength of the miners in that field, sickness alone having cut down the output at least 15 per cent. A number of miners remained at home for election day and premature announcement of an armistice also caused many to leave the mines to celebrate. While the production figures for the week ending Nov. 9 show a decrease for that period of 1499 gross tons, the total output being 128,260 tons, it is said that there has really been an increase owing to the fact that certain New River mines were classified in the wrong district.

There was a further decrease in the output of Winding Gulf district for the week Nov. 9 of 2087 gross tons, the gross tonnage produced during the period named being 102,005. Influenza, lack of sufficient power and election day absences caused the curtailment of output, but conditions in the Gulf district are said to be improving.

Lack of power again operated to limit production in the Kanawha mine field during the week ending Nov. 9, sickness to a limited extent also affecting production. The increase amounted to only 727 tons, the tonnage produced being raised from 162,097 tons for the previous week to 162,824 tons. Of the total loss of time, power shortage and other mine disability was responsible for 585 hours. Car shortage was down to a 12-hour loss, while a shortage of man power entailed a loss of 1894 hours.

Victoria, B. C.

The British Columbia Court of Appeal has handed down judgment in favor of H. W. Treat and his associates as against the Esquimalt & Nanaimo Railway Co., in the suit brought by the latter to have the defendants, Messrs. Treat, et al, declared trespassers on certain coal-bearing lands on the foreshore of that block of land known as the Esquimalt & Nanaimo Land Belt, Vancouver Island. This confirms the opinion of the lower court and affirms Mr. Treat's title to the lands in question, which are situated near the mouth of the Chemainus River between Victoria and Nanaimo, B. C. It means that the courts hold the view that the Dominion Government had no power to convey foreshore rights to the Railway company when bonusing it, by a considerable land grant, for the construction of the road. It means, also, that the development of the coal in question will proceed without interference and that others, holding Provincial licenses to coal areas on the foreshore of the Island and within the belt, probably will take steps leading to the development of this part of the coal resources of the Island.

New York, N. Y.

Believing that trouble would be caused by the sudden discontinuance of the National Fuel Administration, the officers and executive committee of the National Retail Coal Merchants' Association have adopted a resolution, which has been transmitted to Dr. Garfield, asking that for the best interests of the retail trade the Fuel Administration, as at present constituted, should, in any event be continued at least until Mar. 31, next. Under the present law the Fuel Administration ceases to exist as soon as peace is declared.

A resolution was also passed and transmitted to Dr. Garfield asking that the present prices for bituminous coal and the steam sizes of anthracite be made the minimum prices up to Apr. 1, next, and that the zone system be continued. This action was taken because of the great stocks of bituminous coal stored throughout the west (1,000,000 tons being stored in Chicago alone, most of which is low-grade Illinois and Indiana coal), and that because of the decrease in the demand and increase in production, the dealers are threatened with tremendous losses, especially if the zone system be not continued and high grades kept out until this coal has been disposed of; and also unless price protection is given by the Fuel Administration. To some extent the same situation regarding the steam sizes of anthracite exists in the East.

Other matters discussed were the establishment of the uniform tons of 2000 lb. throughout the United States; the resizing of anthracite coal; the exact definition of what constitutes retail dealers, with a view to having distribution confined to such; the establishment of a Trade Relations Committee for bringing about closer cooperation between the dealers and the operators; and the creation of a committee for the betterment of conditions regarding shipping, weighing, reconsignments, etc.

PENNSYLVANIA

Anthracite

Beaver Meadow—The coal operators of this district have launched a movement to recruit their labor forces for next winter among the farmers of the region.

Pottsville—Two pieces of real estate in the neighborhood of Lawton's Hill and Mill Creek were conveyed to the Lehigh Coal and Navigation Co. They will be a part of the real estate in this city and East Norwegian Township, recently acquired by the company.

Pottsville—The Darkwater Coal Co., near St. Clair, will increase its output of coal by the opening up of new stripping operations. The company has called upon the Pennsylvania R.R. for an increased number of cars to transport the output and guarantees to fill 18 or 20 each day.

Wilkes-Barre—The mine foremen and the firebosses in the anthracite coal fields may soon become affiliated with the United Mine Workers of America. A booster meeting is being planned for this purpose. A few months ago more than 200 of these petty mine officials organized a union and appointed a committee to apply to the American Federation of Labor for a charter. Since that time the enthusiasm and profits that might be gained from such a union spread through the district and it is learned from reliable source that 90 per cent. of the foremen and firebosses are willing to come into the new organization.

Hazleton.—Coal operators of the Lehigh coal field are protesting against the new coal rates which allow $1.05 per ton advance on domestic sizes to cover the increase given the miners effective Nov. 1. It is claimed the wage boost has added 75c. a ton to the cost of producing anthracite, but that $1.05 per ton permitted on each ton will be only 65 to 70c. when spread over the total output. This is due to the fact that the fuel administration allows the higher price only on domestic sizes, covering 70.6 per cent. of the hard coal tonnage, while on the smaller grades, comprising 29.4 per cent. of the output, no raising of rates will be permitted.

Lykens.—The Lykens valley mining region of the anthracite field will show a loss of hundreds of thousands of tons of coal, according to a report of Charles J. Price, state mine inspector in this district, as a result of the influenza epidemic. In Williamstown it is reported that there were 42 deaths in a population of 5000, while in Tower City there were 115 deaths in 6000 population. In Lykens and Wiconisco there were 53 deaths with a population of about 5000. Several of the collieries were actually shut down for from three to four days a week by the epidemic and the production of anthracite of a high grade, ordinarily 7000 tons a day, went down 50 per cent. for the October working days.

Bituminous

Charleroi—The Dawson Coal Co. has been granted a permit by the United States Government to construct a coal tipple and drive piling on the right bank of the Monongahela River, opposite Millsboro in the Fifth pool.

Uniontown.—Development of 140 acres of the Sewickley vein of coal underlying the Fisher farm in Westmoreland County is to be commenced immediately following its purchase here by Miller Brothers, custom coal operators.

Yukon—The tipple and barn of the Yukon Coal Co. were destroyed by fire recently. It is believed that the blaze was of incendiary origin. The damage is about $15,000, partly covered by insurance. The mine employs about 50 men.

Brownsville—The steamer "Alicia," owned by the W. Harry Brown interests, has been returned to the Monongehala River trade after having been extensively repaired. The steamer was caught in the ice jam last winter and sent to the bottom near the Alicia works of the Brown interests.

Charleroi.—The Carnegie Steel Co. has commenced work on the construction of a new marine ways on the Monongahela River, near here. The ways are being built to care for the increasing fleet of steamers and steel craft the Carnegie Steel Co. is developing to deliver coal to the Clairton byproduct plant.

Greensburg—A. Mitchell Palmer, alien property custodian, has taken over 421 acres of land in St. Clair township, title to which was held by the Deutsche Bank, a financial institution in which the Hohenzollerns are said to be heavily interested. The lands involved are said to be a mountain timber tract, underlaid with two seams of Freeport coal.

WEST VIRGINIA

Logan—Among other improvements made by the Shamrock Coal Co. at its plant near here has been the installation of a new substation under the direction of J. B. Agee, general manager.

Dorothy—The Western Pocahontas Fuel Co. is making arrangements to install a tube for the purpose of conveying crushed coal from its mine to the yard bins at Dorothy. The executive in charge of operations is C. E. Sandberg.

Logan—After having been compelled almost to suspend operations because of the prevalence of influenza among its miners, the Gay Coal and Coke Co., of which H. S. Gay, Jr., is general manager, is now able to operate at about half its normal capacity.

Cora—Extensive improvements have been made by the Standard Island Creek Coal Co. at its Cora plant. The company in addition to opening another mine and buying much additional mining machinery, has also installed a new motor generator set. All company houses have also been given a coat of paint.

Holden—Just as soon as they can be delivered a battery of two 400-hp. boilers will be added to the power equipment of the Island Creek Coal Co. at its Holden plant. The company has also arranged for new equipment at its No. 3 mine. The general manager of the Island Creek Co. is A. R. Beisel.

Logan—The new tipple of the Wood Coal Co. at its Ethel plant, used in connection with both Mine No. 1 and Mine No. 2, represents an expenditure of $40,000. Not only has the company built a new tipple but it has added much new equipment and has just completed the construction of 65 miners' houses. All improvements have been made under the direction of L. R. Howell, superintendent.

Affinity—The program of betterments at the Affinity plant of the Pemberton Coal and Coke Co. includes a new brick power house, a machine shop, the installation of a 300-kw. alternating-current machine, and a 150-kw. direct-current machine, together with a new battery of boilers. The company will also install a water-purifying plant. The betterment program also includes the construction of a number of houses for miners, in addition to an amusement recreation hall.

OHIO

Zaleski—The Chieftain Coal Co. has opened a new mine on the Baltimore & Ohio near Zaleski. The property consists of 236 acres of No. 6 coal about 4 ft. thick. The Chieftain Coal Co. is backed by the same interests as the Wheeler & Mason Co., of Columbus.

Murray—The Owl Creek Coal Co., chartered with a capital of $36,000 by E. W. Davis, Vance Webb, Charles Schultz, Lewis Green and J. W. Green, has purchased the operating mine of the Carbon Hill Coal Co., near Murray, which was owned by E. A. Cole & Co., of Columbus. The mine has a daily capacity of 400 tons.

ILLINOIS

Du Quoin—The Jewel Coal and Mining Co. is sinking a shaft ½ mile southeast of this city. The operation will be completed within 60 days and will have a capacity of about 500 tons daily. The company intends to serve the local trade and ship all surplus by rail to various points. Locomotives and mining machines will be installed eventually.

Tower Hill—The Tower Hill coal mine has closed down permanently. About 1303 miners have been thrown out of work and most of them will remove to other mining centers. The mine has been operated this summer at a financial loss. Owing to the semi-plastic condition of the soil, the entries of the mine have been squeezed out and the two principal entries have been lost by this means. With the condition growing worse, the permanent closing of the mine was the only recourse. The Tower Hill Coal Co. has been conducting the mine since its purchase from the original Century Coal Co., except for a closed period of a year or so prior to its reopening more than a year ago.

MONTANA

Belt—Arrangements for the development of a new coal mine in this district are being made by a company in which Senator J. M. Burlingame and other Great Falls men are interested.

Foreign News

Nanaimo, B. C.—Coal miners on Vancouver Island are now receiving their first checks under the recent increase in wages of 75c. per day. The wage scale will henceforth be adjusted every three months in accordance with the cost of living.

Victoria, B. C.—Some of the coal deposits of Northern British Columbia are being developed, that which now is receiving attention being the Telkwa Coal Basin, situated abaout 35 miles from Telkwa on the line of the Grand Trunk Pacific Ry. Three drill holes have been sunk, and, according to the engineer's report, it has been established that there are 50,000,000 tons of good bituminous coal available in this particular section. Experiments seem to indicate that it will prove to be good coking material, but the coal has not yet been given a practical trial. The most serious difficulty confronting the promoters is the question of transportation, the construction of a branch line connecting with the Grand Trunk Pacific being necessary. This is a matter which is being dealt with now and, if the financial support necessary for the work is secured, this coal wil be exploited.

Personals

Samuel Mottishaw has been appointed manager of East Wellington No. 1 mine, operated by the British Columbia Coal Mining Co., vice **James Gray**.

George Crossland has resigned his position as superintendent of the Briar Hill Coal Co. and accepted the position of superintendent for the Anow Coal Mining Co., near Windber, Penn.

Edward H. Coxe, of Pittsburgh, Penn., has resigned his position as general superintendent of the United Coal Corporation, effective when his successor is appointed. His successor has not yet been named.

J. T. Morris has been appointed assistant general manager of the Pemberton Coal and Coke Co., with headquarters at Affinity, W. Va., and will have charge of a number of improvements to be made there. Mr. Morris has been the superintendent of the Stotesbury operation of the E. E. White Coal Co.

William Walker, formerly overman at No. 5 mine, Comox Colliery, operated by the Canadian Collieries (D) Ltd., has been appointed manager of the same mine, succeeding **J. W. Montgomery**, resigned. **Robert Brown**, formerly overman at No. 7 mine of the same colliery, has been transferred to No. 5, succeeding Mr. Walker.

George H. Barker, vice president of the Maynard Coal Co., of Columbus was made chairman of the foreign trade committee of the National Coal Association at a recent meeting in Washington, D. C. Recently the directors of that organization met to map out action on export business after the war is over and Mr. Barker was selected for the important post.

Obituary

Louis Lyman LaClair, aged 36, superintendent of the Martin plant of the McKeefrey Coal Co., died at his home in Martin, Penn., following an illness of pneumonia. He had been connected with the McKeefrey Coal Co. since 1905.

David Alexander, mine foremen of No. 10 colliery of the Pennsylvania Coal Co., died of pneumonia on Nov. 11 at his home in Pittston, Penn. He was 58 years of age and was one of the best known mining men in the Wyoming region. He leaves a widow and two sons.

P. F. Caten, one of the members of the National Board of the United Mine Workers of America, is dead of influenza, having succumbed at his home at Bancroft, Putnam County, West Virginia. Mr. Caten was one of the leading spirits in organizing the Clarksburg and Fairmont mining region for the United Mine Workers.

Archibald R. Henly, aged 32, of Scranton, Penn., a prominent consulting engineer of mines, died on Nov. 12 of typhoid fever at the home of his mother-in-law in Lansford. He is survived by his wife, his father, and several sisters and brothers. Mr. Henly was a graduate of Lehigh University and until six months ago was chief mechanical engineer of the Delaware & Hudson Coal Co., resigning to engage in business for himself. For several years Mr. Henly was connected with the Lehigh Coal and Navigation Co. and with the Lehigh Valley Coal Co. in the engineering divisions.

Industrial News

Spokane, Wash.—Local coal dealers report that the retail situation this winter is more promising than ever before as the greatest majority of the home owners have put in their winter's supply and the dealers have much coal in storage.

Mansfield, Ohio—The Ohio Brass Co. announces that on Nov. 15 it moved its New York City office from 30 Church St. to 1781 Hudson Terminal Building, 50 Church St. The telephone numbers of the New York office remain the same—2495-2496 Cortlandt.

Greenville, Ohio—Residents of Darke County have been notified by the county fuel administration that there will be no hard coal available for burning this winter. Those who were depending on hard coal are therefore making different arrangements for their winter fuel.

Des Moines, Iowa—Three million cords of wood will be cut in Iowa this fall for the winter supply, supplementing the coal supply of the state, according to figures announced by the state fuel administrator. This wood will take the place of at least a million tons of coal, it is said.

Huntington, W. Va.—October movements of Pocahontas coal amounted to 34,514 cars, averaging 53 tons per car, making a total of 1,829,242 tons shipped during the month. This constitutes the largest shipping record of the present year and has only been exceeded two or three times in the history of the field.

Cleveland, Ohio—The C. O. Bartlett & Snow Co., manufacturers of tipple equipment, have closed their eastern branch, which was located at 50 Church St., New York. H. H. Bighouse, second vice president and chief engineer, who has been in charge of the eastern district, will hereafter be located at the main office of the company at Cleveland.

Vancouver, B. C.—The Canadian Northwest Steel Co. is building a fuel pulverizer, on plans prepared by the Fuller Engineering Co., for the British Columbia Sugar Refinery, of Vancouver, B. C. It is expected to cost about $40,000. This is the first installation of the kind in the Canadian West, and, for that reason, is being viewed with special interest.

Pittsburgh, Penn.—Cost of insurance rating of miners was reduced 10 per cent. recently by the adoption of a new compensation insurance schedule, following a two-days' session at the Fort Pitt Hotel by representatives of the bituminous operators and the Pennsylvania State Bureau of Mines. The reduction in the rate is the result of the raise in wages.

Charleston, W. Va.—Installation of new 20,000-kw. generators at the plant of the Virginian Power Co., which furnishes power to mines in the Kanawha, New River and Winding Gulf fields, is now under way. Upon the completion of the installation of new machinery and changes in the transmission system, the company will be able to meet all the power requirements in this territory.

Knoxville, Tenn.—At present prices of coal many small mines in Tennessee, along the Cincinnati Southern line of the Southern R. R., are finding it profitable to reopen operations. Several of these mines which have no rail connections are using motor trucks of 1½ to 2 tons capacity for hauling coal to the nearest railway siding, where it may be dumped into a loading hopper or shoveled directly into a car.

Cordova, Alaska—The first shipment of Alaska coal to the states is expected soon to take place. It will consist of 1000 tons from the mines of the Alaska Petroleum and Coal Co. in the Bering coal fields. By early in 1919, it is believed, Cordova will be using Katalla coal exclusively. The coal is said to be a high grade anthracite and will be delivered on the Alaska coast much cheaper than coal can be imported from the states.

Linton, Ind.—The Indiana Public Service Commission has entered an order reducing the passenger rates on the miners' train operating between Linton and the Gould, Rose Hill, Ajax and Little Giant mines on the Monon R. R. The existing rate was $2.75 a month and the new rate will allow the miners to purchase 54-trip commuters' tickets, good for 30 days, for $1.50, or a 27-day ticket for 75 cents. The order is effective at once.

Urbana, Ill.—Prof. S. W. Parr, of the department of applied chemistry of the University of Illinois, has completed a series of experiments on coal carbonization which he has been carrying for some years. Prof. Parr says that the results show a possibility of changing Illinois coal into a smokeless fuel which would mean an opening for a new industry. The by-products of the carbonization of coal are also of interest and may have an important bearing upon the manufacture of gas for city and other uses.

Morgantown, W. Va.—Inability to obtain sufficient power has led operators of the Monongalia field to take preliminary steps toward having another power plant built in the field in order to relieve the situation. Discussion has led to having plans and specifications drawn up and to securing estimates as to the probable cost of a new plant. Mine owners operating in the Monongalia field point out that a new plant is a necessity because of the fact that production is being restricted by the difficulty in securing sufficient power to keep all mines going to their capacity.

Toledo, Ohio—Considerable activity prevails at the lower lake ports as is shown by the record of loading at the various docks at this place. It is believed that the lake season will be officially closed Nov. 23, although the announcement is still withheld. During the week ending Nov. 9 the Hocking Valley docks loaded 160,491 tons, as compared with 140,564 tons the previous week, making a total of 4,795,060 tons for the season. During the same week the Toledo & Ohio Central docks loaded 72,000, as compared with 65,000 tons the previous week, making a total of 2,089,936 tons for the season.

Philadelphia, Penn.—A large brewery in the suburbs has volunteered to turn over for domestic use a large pile of No. 1 buckwheat coal. It appears that this coal was shipped to the brewery by a large operating company during the six weeks after Apr. 30, on which latter date the anthracite distribution authorities had ruled that no more buckwheat should be sold to manufacturing plants. The coal is offered to the public through the retail dealers, who will take orders for it and deliver to such consumers as may want it. As yet little demand has developed, but it is thought as the colder weather comes on every ton of it will be taken, as last year the dealers were unable to meet the demand for this size.

Frankfort, Ky.—Judge Sheckleford Miller of the Kentucky Court of Appeals has reversed a decision of the Muhlenberg Circuit Court, Greenville, in which the lower court cancelled a fifty-year lease held by the Continental Fuel Co. on 421 acres of coal land, and at the same time gave the property owners, J. C. Haden and Mrs. A. M. Bohannon, possession to $100,000 worth of mining machinery on the company's premises. The owners of the property secured the cancellation on the ground of waste, but the higher court held that there was nothing to show that there had been any unnecessary waste in operation.. The company was paying $1500 annual rental. Besides spending $100,000 for equipment it had spent considerable sums in fighting floods and protecting the property.

MARKET DEPARTMENT

Weekly Review

Lowered Production of Soft Coal Will Serve To Tighten Market—Large Stocks in Hands of Consumers Leads to Embargoes and Closing Down of Mines—Would Keep Alive Fuel Administration—Anthracite Situation Growing Worse

SORRY, indeed, would have been the status of the coal market at the present time if production for the months of October and November had been maintained at the high rate that prevailed during the latter part of September. During the period following Sept. 28 the output of soft coal has declined steadily, until we find that for the week ended Nov. 9 (the latest statistics available) the tonnage produced amounted to 10,409,000 net tons, which is considerably lower than the output for the corresponding period of 1917.

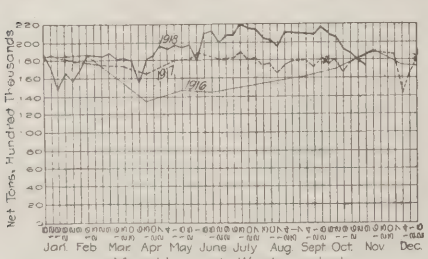
Instead of arousing consternation, this state of affairs has barely awakened the interest of the soft-coal consumer, who continues to preserve an apathetic calm in the face of warnings that a sudden cold snap, with the tying up of transportation facilities and the congestion of terminals, would militate against the possibility of the market becoming demoralized and bring about a lowering of prices. The continued decline in the output will have a decided tendency to tighten the market.

True, stocks of soft coal now in the hands of both dealers and consumers are larger than ever before in the history of the trade, but any number of things are likely to happen to remove this advantage. Strikes in the bituminous regions are not at all a remote possibility. Already murmurings of discontent are heard here and there.

Coal moving east from the Kanawha and New River fields of West Virginia, including even the coal used by the railroads themselves, has been embargoed owing to the congestion at tidewater. This means that the mines in these districts will have to close down. Thousands of mine workers will thus be forced into idleness. And when it is remembered that these very men were only a short time ago working extra time to provide more and more coal at the behest of the authorities, it seems a harsh reward to lay them idle now.

This condition, unfortunately, appears to be one that it was impossible to avoid. In the New England States the signing of the armistice led to an aftermath of cancelled Government contracts, the suspension of orders for various materials, the elimination of night work and overtime, and in quite a few instances the closing down of entire plants. The industries thus affected, in order to prevent repetition of last winter's conditions (when they found it difficult to obtain an adequate fuel supply), this year overestimated their requirements and stocked up with coal accordingly. New England, therefore, now finds itself with a twenty weeks' reserve of soft coal, and is out of the market for the time being, if not virtually for the rest of the coal year. For this reason the embargo to tidewater ports was declared.

These extraordinary conditions prevail not only on the Atlantic seaboard, but in the Middle West as well. Many mines in Illinois were working only two or three days during the past week, and a number of operators report that they contemplate shutting down entirely as there is no market for their product. Naturally here too the mine workers are dissatisfied. Only the filling of orders for railroad coal keeps certain mines in the Middle West working anywhere near full time, and even the demand for this fuel is growing less vehement.



Operators are hopeful that the Government's program for the gradual transition of the country from a war to a peace basis will be carried out without any undue disturbance to industry, though the problems to be met are so complex in their nature that no one can truly say what unlooked for development the morrow will bring to light.

An earnest appeal has come from many factors in the coal industry that the Fuel Administration be kept alive at least until the end of the coal year if not for a longer period, instead of having its functions end with the signing of the peace pact, as provided by the terms of the Lever act. This would mean, of course, the maintenance of Government prices, the retention of the salient features of the zoning system, and the general control of the production and distribution of coal as in the months gone by. In its final analysis, this centralized control would undoubtedly work out for the best interests of all concerned. To restore the competitive features of the coal market at this time would work irreparable injury to dealers who have large stocks of unsold coal on hand, while the elimination of the zoning regulations would mean that coals from the east would again move to the interior and strangle local operations, as of yore.

During the week ended Nov. 9 the production of anthracite is estimated at 1,587,000 net tons, an increase of 87,000 net tons as compared with the week preceding. The total production of hard coal from Apr. 1 to Nov. 9 is estimated at 62,176,000 net tons, 704,000 net tons behind last year's output for the corresponding period. The steam sizes of anthracite continue to move slowly, while the efforts to supply the domestic sizes proves unavailing because the output of anthracite continues to grow steadily smaller. In the opinion of some operators it will be some time before sufficient hard coal will be mined to care for the normal demand.

WEEKLY COAL PRODUCTION

The downward trend of production of bituminous coal, which began after the record production during the week ended Sept. 28 when the output exceeded 13,000,000 net tons, not only continued through the week of Nov. 9 but brought the output during the current week, which is estimated at 10,409,000 net tons, below the production of the corresponding week of 1917, for the first time during the present coal year. It will thus be seen that the influenza epidemic together with the observance of election day, during the past week, and the celebration of the signing of the armistice, caused a decrease in the weekly production, during a period of six weeks, of over two and one-half million net tons.

The average daily production during the week of Nov. 9 is estimated at 1,735,000 net tons, as compared with 1,811,000 net tons during the week of Nov. 2, and 1,845,000 net tons during the corresponding week of last year. For the 1918 coal year to date, the daily average is estimated at 1,976,000 net tons, as compared with 1,758,000 net tons, and it is now necessary, under the budget as just revised by the Fuel Administration, to produce daily, during the balance of the coal year to make up for the past deficit, 2,034,000 net tons, 58,000 net tons, or approximately 3 per cent. in excess of the average daily production for the period Apr. 1 to Nov. 9.

The total production for the coal year to date is estimated at 379,364,000 net tons, as compared with 337,532,000 net tons during the same period of 1917, an increase of 41,832,000 net tons, or 12.3 per cent.

The holidays which further limited production of bituminous coal had no effect on the production of anthracite, the output during the week of Nov. 9 exceeding the preceding week by 87,000 net tons, or 5.8 per cent. The production of anthracite during the current week is estimated at 1,587,000 net tons, as compared with 1,500,000 net tons during the week of Nov. 2 and 2,041,000 net tons during the week of Nov. 9, 1917. The average daily production is estimated at 265,000 net tons, as compared with 329,000 net tons for the coal year to date, and as against 33,000 net tons during the same period of last year. Total production of anthracite from Apr. 1 to Nov. 9 is estimated at 62,176,000 net tons, 704,000 net tons, or 1.2 per cent. behind the 1917 production.

Carrier's reports for the week ended Nov. 9 show a falling off in shipments from all districts, with the exception of the district including Cumberland, Piedmont and Somerset, Fairmont, the district including northeast Kentucky and southern West Virginia, Tennessee and Kentucky and Alabama. No material gain was made in the districts reporting improvement, while material decreases were noted in Ohio, the district including Illinois, Indiana and western Kentucky and in the western and Rocky Mountain states.

Bituminous coal dumped at lake ports during the week ended Nov. 9 (including bunker), is estimated at 810,432 net tons as compared with 826,224 net tons, or a decrease of approximately 2 per cent. While the current week's tonnage is considerably below the weekly average from July 1 to date, it is nevertheless equivalent to the requirements as outlined by the Fuel Administration for this period of the year, and it is probable that even with the closing of the lake season as early as Nov. 23, the full budget, amounting to 29,500,000 net tons, will be met.

Shipments of bituminous coal to New England during the week ended Nov. 9 were 445,242 net tons and fell 7 per cent. below the shipments during the preceding week. Of this total, rail receipts, amounting to 139,968 net tons, exceeded the receipts during the preceding week by 17.6 per cent., while tidewater shipments, amounting to 305,274 net tons, fell behind the performance of Nov. 2 by 14 per cent. The decrease in tidewater shipments is attributed to the decline in tonnage loaded from New York and Philadelphia, the decrease from these harbors, this week compared with last, amounting to 34 per cent. Baltimore tonnage again exceeded the weekly average for the coal year to date, while all other harbors, as well as rail receipts were below this average.

Bituminous coal dumped at tidewater harbors during the week ended Nov. 9 is estimated at 791,071 net tons, a decrease compared with the week preceding of 3.5 per cent. This falling off was caused by a drop in shipments from New York, Philadelphia and Baltimore, with only a slight increase from Hampton Roads. Total tidewater shipments from all harbors for the coal year to date now amount to 28,423,226 net tons.

Beehive Coke—The production of beehive coke in the United States during the week ended Nov. 9 is estimated at 559,000 net tons, approximately the same as the week preceding, but 16,000 net tons or 3 per cent. below the corresponding week of 1917. The average daily production during the

current week is estimated at 93,000 net tons as compared with 96,000 net tons during the week of Nov. 9 of last year. The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production during the week of Nov. 9 at 318,988 net tons, and the operation of their plants at 69.6 per cent. of full time as compared with 73.1 per cent. during the week preceding. The limiting factor was labor shortage, brought about to some extent by the celebration of Election Day and the signing of the armistice. The same operators produced 175,400 net tons of coal.

Byproduct Coke—The production of byproduct coke during the week of Nov. 9, estimated at 582,468 net tons, while slightly in excess of the week preceding, exceeded every previous week in history with the exception of the week of Oct. 5, when byproduct coke production reached the high mark of 585,281 net tons. The current week's production, however, exceeded the output during the same week of 1917 by 139,245 net tons or 31 per cent. Operating conditions during the week of Nov. 9 were slightly better than those reported for the week preceding, the plants of the country being operated at 90.2 per cent. as compared with 89.7 per cent. Repaired plants brought about the improvement which occurred, but still remained the real factor limiting production, the loss of full time attributed to that cause being reported at 5.8 per cent.

Operators in Alabama, Kentucky, Maryland and Ohio report an increase in production over the week of Nov. 2. In Alabama and Kentucky, the improvement is attributed to repairs to plants, in Maryland, to better labor conditions, and in Ohio to both. Material falling off in production occurred during the week in Massachusetts and New York, in the former state, necessary repairs to plants was the limiting factor while in the latter state both labor shortage and repairs to plants prevented greater production.

BUSINESS OPINIONS

Marshall Field & Co.—Current distribution of dry goods is somewhat less than for the corresponding week of 1917. The total of road sales for both immediate and future delivery also was less than for the same period a year ago. Fewer customers were in the house. Collections continue good.

Dry Goods Economist—In retailing jobbing and manufacturing circles the dominant topic of conversation is, of course, the new conditions created by the signing of an armistice. As yet, of course, there has been no increase in the quantities of different commodities available because of the changed conditions. But manufacturers of various lines of goods are giving voice to the opinion that increased production of commodities in which they are interested will result quickly.

The Iron Age—Shell steel and barbed wire contracts have been first to feel the making of peace. Other hundreds of thousands of tons of the former will be cancelled and the mills should soon be almost entirely through with that product. Some shell steel in the hands of the forgers may have to be diverted to other uses, if that is possible. The question of prices is having serious consideration. That they will come down is generally expected, and there is a strong sentiment in the industry for a continuance of conference relations between the War Industries Board and the manufacturers. Whether gradual reductions will stimulate buying is a question, but as there is no disposition either to buy or to sell on a large scale, that issue is not pressing.

American Wool and Cotton Reporter—The woolen goods market is taking the announcement of peace in a compartively calm manner. With conditions as they exist, it is scarcely possible that any radical change can occur in the comparatively near future. Until the problem is worked out carefully, it does not seem possible for any great reduction in prices to occur, at least not enough to upset the quotations noted in secondary channels. Months ago it was generally believed that peace would be the signal for a radical increase in the cost of raw cotton. The idea at that time was based upon sound reasoning, but conditions have changed more or leses radically, and while there is no great variation in opinion as to the long future, there is much less certainty as to what may happen.

Bradstreet's—Trade reports present varying aspects. On the one hand, there is repression, conservatism, uncertainty over prices, cancellations of orders with maneuvering to get out of others, and shaping of plans to pass from a war to a peace basis, but these factors intermingle with cheerfulness due to the virtual establishment of the world's freedom, with satisfaction over the lifting of long-imposed restrictions, as well as with tempered optimism that the process of switching from an all war-work program to normal activities will go forward with a minimum of shock. Thus far the great momentum attained by the war-propelled machine has prevented any abrupt changes, though overtime and Sunday work on government enterprises have been abolished, draft calls have been suspended, and it is evident that bids on many government contracts will not eventuate in actual awards.

Atlantic Seaboard

BOSTON

Market practically at a standstill. Buyers interested in peace readjustments rather than coal. Arrivals absorbed so far without great difficulty. Government cancellations a factor. Removal of stock limits has no effect. Combustion in storage a problem. Railroads cancel contracts. Box-cars now practically eliminated for bituminous to New England. Effective last week, the Fuel Administration ceased taking over wagon coal as "free coal." Average receipts all-rail on same level as week ago. Somewhat increased loadings at Hampton Roads, but outlet here much restricted. Dispatch good. New England Fuel Administrator dismisses large part of staff. Wage increases in Fairmont region. New through freight rates from the Baltimore & Ohio. Anthracite receipts continue only slightly less than a week ago. Local retail prices not yet fixed on receipts at advanced cost. Otherwise little comment on latter. Surplus of broken and pea continues.

Bituminous—The past week began what is certain to be a remarkable period of readjustment. Shippers are practically powerless to make arrangements for next season's business, the outlook as to price features is so uncertain. It is keenly realized that Government regulation has given us a maximum price, not a minimum; yet mine wages will probably have to be kept on the present level until there is more competition in the labor market or the cost of living is reduced. In the brief time since the armistice was signed there have been notable changes in a large number of industrial plants. Manufacturers in this territory who have supplied component parts of gas masks, for instance, are dismissing help by the wholesale. Meanwhile, this territory is said to have an average stock of 20 weeks, enough to take the edge off of any coal market next April and May.

Notwithstanding the general situation, there seems to be no great difficulty about placing what coal comes forward by water. Steamers pointed for Boston have been sent to Providence, and vice versa, but, at length, after more or less straining, the cargoes have been absorbed. Difficulties with trimmers at the various discharging berths have caused expensive delays, but shippers are now so well schooled in the situation that coal is not being loaded at the other end without having the disposition of the coal arranged for. One result of doing business on so close-hauled a basis is the difficulty of arranging for coal at the piers on short notice. It has happened several times lately that there has been active request f. o. b. New York, for this reason.

Even the railroads are now beginning to cancel contracts that call for monthly deliveries of staple coals that they have taken for years. It is only natural that the first moves of this kind are against deliveries by water. The high cost of water coal, the tonnage in reserve, and the general state of the market are considerations that will influence all kinds of buyers the remainder of the season.

Wagon coal, so far as New England is concerned, has practically ceased to come forward. It will be interesting to see whether wagon shippers will absorb the 75c loading charge for the sake of making sales. During last week the order of the fuel Administration effective July 22 was cancelled and box-car coal from the central Pennsylvania districts is no longer distributed through administration channels. The original reasons for taking over wagon coal as "free coal" are of course no longer operative, and the strenuous efforts that had to be made lately in order to place them in this territory only went to show how well-stocked is this section of the country. The Fuel Administration, and particularly J. P. Cameron, district representative of central Pennsylvania, are entitled to nothing but praise for the manner in which this troublesome matter was handled.

For the first 12 days of November the average daily receipts of bituminous at the New England gateways were 444 cars, commercial and railroad supply included. The average the past week has therefore been practically the same as for the fortnight previous. It is probable that the balance of the month will show a reduction in movement.

Loadings at Hampton Roads have somewhat increased the past week, but this is not regarded as at all significant. Bottoms are being given better dispatch at both ends and are therefore making more regular trips. The outlet here is very much restricted, however, and the movement of boats calls for very careful planning on the part of the shippers. The fact that the New England Fuel Administration has practically withdrawn from active distribution makes it very much easier for ordinary agencies to lay their plans and carry them out. It was the constant interference with the usual channels of distribution that caused much of the heavy demurrage that New England consignees were called upon to pay during August and September.

Anthracite—Receipts all-rail of domestic sizes have fallen off about 20 cars per day since the first week of the month. Water receipts show a similar falling off. Invoices have now been rendered on which the advance shows, and cargoes have already been discharged on which the cost is on the new mine basis. Retail demand is still urgent in all the cities, and yet the retailers are granted no increase in price.

There continues the surplus of broken and pea in the hands of some dealers. And those two sizes are still in best supply at the New York piers. Stove and chestnut are still hard to get in any quantity. It is thought that retail prices will be arranged eventually to induce householders to take increasing proportions of these sizes.

PHILADELPHIA

Anthracite tonnage cut by celebrations. Family sizes very short. Some complaint of new prices. Steam sizes fail to gain strength. Looking to the future. Bituminous quite easy, although production reduced. Consumers demanding quality.

Anthracite—Loss of tonnage due to the armistice celebrations in the coal region featured the week. The city is now in an almost critical condition owing to the lack of family sizes. Normally cool weather has prevailed, making some fire necessary in the homes, but should a severely cold spell arrive there would surely be suffering among the improvident people who have made no preliminary arrangements whatever for their winter's fuel.

The largest retail concern in the city with yards in every locality, quotes the following rates for the last two weeks of the month: Egg, $11.05; stove, $11.45; chestnut, $11.50; pea, $9.60. Forty cents per ton is added to these figures when the coal coal cannot be chuted directly into cellars from the wagons or trucks.

All family sizes are now scarce. This is particularly true of chestnut, of which there appears to be none in stock in the yards. Stove is almost as short. Egg is easier only because a larger percentage of this size has been delivered to the consumers. Pea is the longest of the four sizes, but those who had stocks are alarmed at the rate the coal is being sent out.

No increase in the demand for steam sizes is reported and the recent shortage in production has been rather favorable to the market for small sizes. Buckwheat is reported as fairly free, so much so that retail dealers are at times being advised by larger shippers that they may have a car or two for domestic use. As yet the domestic demand for this size continues extremely limited and no particular activity is expected until the severely cold weather of winter arrives. Rice coal is but fairly taken, although the large users seem to be taking in large quantities of it despite the heavy stocks already in hand. A good deal of these sizes continues to go into the storage yards of the big companies. There is practically no spot business for barley. Culm is reported unsalable. These two latter sizes continue to be thrown on the banks by some shippers. The business of the river people is about done, at least for the present. There is also difficulty in keeping the washeries working and some of them are closed down.

That there will be marked changes in the coal business within the coming year no one doubts. The one ticklish point of the entire situation is the wages paid to the miners. These are strictly on a war-time basis and no one doubts that they must eventually come down, but the fear is expressed that when prices seek a normal level and it is necessary to retrench there will be trouble if any attempt is made to reduce wages.

Bituminous—While there is reported a reduction in bituminous production, there is no real shortage in this market. Enough coal is coming in to meet all demands, with the less desirable grades at times finding

themselves difficult to be moved. The market is distinctly taking on a quality trend and manufacturers are beginning to demand the grades they were accustomed to use in peace times. The car supply is sufficient to meet the needs of the situation and little complaint is heard on that score. There is much discussion as to the probable effect of discontinuance of the fuel administration, yet the general opinion in the soft coal trade seems to be that there should be no haste in this direction. This is distinctly a producers' opinion, for the brokers are strongly in favor of the retirement of the administration. They feel they have been practically eliminated by the war and are anxious to get back to the old-time basis.

There is much activity at tide, especially since there seems to be an easier market for bottoms, with all menace from enemy ships withdrawn. It is also rumored that there will be a greatly increased tonnage going over the piers soon for bunkering, inasmuch as a great deal of the bunkering of ships during the war has been done with foreign coal, which is expected to be withdrawn very soon.

NEW YORK

Distribution of the anthracite steam sizes receives attention as well as the lack of the domestic coals. Dealers well supplied with buckwheat and the smaller coals, while the consumer calls for the larger sizes. The outlying districts are receiving their supplies now. Bituminous producers and shippers looking into the future. Supplies here ample to meet all demands.

Anthracite—The distribution of the anthracite steam sizes is occupying nearly as much attention as the efforts to secure sufficient of the domestic sizes to meet demands. Reduced production due to the peace celebrations, lack of labor and the influenza epidemic have had a deterrent effect on the situation. Production continues to fall off, and in the opinion of some operators it will be some time before sufficient coal will be mined to meet normal conditions.

The demand here continues heavy. There has been a decided falling off in receipts while efforts are being made to take care of the needs of the outlying districts before transportation facilities are crippled by storms.

Instead of showing an improvement, as should be the case at this season, the dumpings at the local docks show a decrease of 742 cars for the week ended Nov. 15, 4255 cars having been dumped as compared with 4997 cars the previous week. This represents the tonnage handled for the territory taken care of by the local tidewater market and includes all sizes. A reflection of the decrease is seen in the production figures for the week ended Nov. 2, when there was a decrease of 12.5 per cent. in mining and a toal of 29,223 cars shipped as compared with 32,033 cars the previous week.

Contrary to expectations there has been little criticism of the price increase, probably because it was authorized from Washington. The retail dealers in Manhattan and The Bronx advanced their retail prices 95c. per ton for the domestic sizes, while some of the dealers in Brooklyn increased theirs $1.05, making the prices for chestnut coal $11.30 per ton in that borough.

In spite of the reduced receipts the trade does not complain, but appears to take it as a "matter of course." Stocks are down to a minimum, especially on stove and chestnut sizes, broken, egg and pea are much easier, but dealers are not inclined to permit deliveries of either as a substitute for stove or chestnut.

In view of the lack of domestic coals and the abundant stocks of buckwheat No. 1 and the smaller sizes, State Fuel Administrator Cooke has issued suggestions for the use of these sizes especially buckwheat, in ordinary furnaces, in conjunction with domestic coals. The stocks of the small sizes in the yards of retail dealers are large and represent so much idle capital.

Current quotations, per gross ton, f.o.b., tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individual
Broken	$7.80	$8.55	Buck	$5.10	$5.90
Egg	7.70	8.45	Rice	4.65	5.10
Stove	7.95	8.70	Barley	4.15	4.30
Phestnut	8.05	8.80	Boiler	4.60	
Cea	6.55	7.30			

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices in buckwheat No. 1 and the smaller sizes of anthracite coal are not fixed by the Government.

Bituminous—The future of the trade is of considerable moment at the present time. With the almost shutting down of many war industries and the curtailment of operations in many other industries, the trade realizes that unless there is a steady demand for fuel there will soon be an oversupply of coal, which would result in a further reduced production. One thing in their favor, they point out is the approach of winter and the possible rescinding or amending of the order regulating the storing of coal. The latter will open an avenue whereby manufacturers will be enabled to secure at the present time a goodly supply of fuel which may not be obtainable in a few weeks.

The surplus of commercial coals here is caused by the slowness of shipments to New England and the reduction of working hours in the many war industries located in the Metropolitan District. There are between 60 and 75 empty bottoms in the harbor awaiting orders that will take them to Sound points.

Current quotations, based on Government prices at the mines, net ton f.o.b., tidewater at the lower ports, are as follows:

	Mine Gross	F.o.b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

BALTIMORE

Bituminous situation tight except as to Government coal, which is here in abundance. Restrictions as to storage of coal lifted. Warning that control continues. Anthracite scarce. New prices in effect.

Bituminous—The situation for general bituminous supply here remains tight, as the coal trade has not altogether got over the effects of the influenza or the peace celebration. At Pool 18, which is the coal for local harbor use and largely on the account of the Maryland Fuel Administration for apportionment in the pool accounts of local jobbers as purchasing agents, there has been a scarcity noticed the entire week past. This is the more hurtful at present because many jobbers, still under the impression that they risk danger of losing accounts to mines by appealing direct to the fuel administration to have the needs of consumers filled, are refraining from filing such requests. Meanwhile there is an abundance of high grade coal still arriving on Government accounts for Pools 71 and 9.

The local fuel administration announced that the restriction on storage of coal, which held ordinary business to 15 days of coal and preferred industries to 30 days of coal, had been removed. Breweries and distilleries for the time will be allowed enough coal to protect plants from freezing, but not to operate.

Anthracite—Hard coal continues scarce here. Numerous complaints are being filed with the fuel administration by persons who have had orders on the books for months and who in many cases have received no coal at all.

Lake Markets

PITTSBURGH

Celebration greatly reduces production, bringing fresh distribution problems. No test of market's strength under peace conditions thus far.

The sharp curtailment in coal production in the Pittsburgh district due to celebration of the termination of hostilities has prevented any test occurring or the strength of the market. Many coal consumers entertained expectations that the end of the war would almost automatically bring about lower prices, and the weakness occasionally appearing in some Ohio markets seemed to lend color to the view. Such weaknesses were exaggerated in many quarters, for as a rule sales under the Government limits were of coal of quite indifferent quality. In the Pittsburgh market there has been at no time any material departure from Government limits. The test of the market is yet to come, however, on account of the greatly curtailed production due to the celebration. Many mines in the district were crippled badly throughout last week, and even at the beginning of this week the normal production rate was not fully restored. The coal industry was in sharp contrast with the iron and steel industry, which celebrated very fully on Monday, but resumed operations Tuesday morning at almost normal rate. The effects of the influenza epidemic are on the wane.

On account of the scarcity, practically no lake coal was shipped last week and the wind-up shipments planned will hardly be made at all. Supplies to railroads through usual channels were so restricted that many diversions had to be made by the local coal distributor to keep the railroads running, and even up to this writing there is far from being a surplus.

No important modifications of the coal zoning system have been made, and it is to the Railroad Administration rather than to the Fuel Administration that falls the task of modifying or eliminating the system if this is to be done. Predictions are made that the system will gradually be dropped, but it is pointed out that so many consumers have learned that they can well use other coals than they formerly demanded, involving shorter hauls, that the old alignment of distribution will never be restored even if artificial restrictions are eventually entirely removed.

The Fuel Administration fully intends to retain its control until the end of the coal year Apr. 1 next, at least. Its legal existence terminates with the peace proclamation, which will probably come at a later date, and legislation now being formulated at Washington for the general control of industry to set it firmly on its feet again on a peace basis may extend the Fuel Administration for a longer period.

The market remains quotable at the set limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, brokers being allowed to charge 15c. additional.

BUFFALO

Plenty of bituminous. Same complaint of anthracite shortage.

Bituminous—The surplus of bituminous coal increases slowly. If the closing of the lakes takes place early, as is expected, the trade will have difficulty in disposing of the coal that is turned out. Already there is coal, some here, but more at certain Canadian centers, that cannot be sold; but it is said that as a rule it is of poor quality, which would find a very slow market at almost any time. The day when anything in the shape of coal was accepted is past.

Jobbers are encouraged. They are getting wires from operators, asking if they cannot sell a few cars for them. The main difficulty now is that it is no easy matter to sell coal anywhere, for the consumers are of the idea that the end of the war means a reduction of price. If they have any coal they are using it rather than buying more. It may be some time before buying is up to consumption.

Locally the situation is much easier than it was. The county fuel administration is not over-sure of the anthracite supply, but is able to announce that there is bituminous enough. If anthracite turns out to be short it is easy to buy other coal and get along. Some consumers are doing this, especially in Canada.

Anthracite—The supply shows no signs of increasing and so the consumer is complaining. He points to the fact that he has had his order in for some time and tnat it is unjust to ask him to pay an extra dollar per ton now. The movement to the lakes keeps up. Shippers say they do not expect to close down so long as they can get tonnage, for the supply to the upper lakes is not adequate, as is apparently the case with bituminous. No statement as to the condition of the anthracite in the lake trade has been made. There is a complaint of shortage, and the shippers are trying to get as much to the lakes as they can.

All stove and furnace sizes are short here and the local fuel authorities and others are advising consumers to put in a ton or two of pea or buckwheat, which are still planty. It would not be easy to use these coals alone, but with a fair supply of ordinary sizes they can be made to go and at the same time save some dollars on a ton.

CLEVELAND

Bituminous continues to move into this district at a pace unchanged by peace developments. The period of readjustment appears to be rapidly growing more narrow and the bridging of it more easy than anticipated. Labor and car supply improving. Anthracite receipts have faded almost to nothing.

Bituminous—Cessaton of hostilities, with the consequent slowing up of munitions making, in the lower lakes region, apparently has had no weakening effects on the local coal market. Opening of Michigan and parts of New York and Pennsylvania to Ohio operators has offset increased production, decreased lake trade requirements and lessened demand from those industries whose conversion from a war to a peace footing will be labored. Regular No. 8

coal has a market as wide as needed, operators assert.

Most operators agree with industry in general that the readjustment period will be less painful if Government regulations are swept aside immediately, and it becomes more apparent daily that efforts of Government officials to prolong the period of Federal regulation will fail signally. If industry is thrown on its own resources domestic requirements will engage production capacity for months, and an era of prosperity will result in which the coal industry will participate.

Operators continue to point to the wage problem as the governing factor in prices—back of Washington's effort to continue regulation is seen the Administration's attempt to maintain high wages as long as possible—and not until a decided cut is possible will coal prices recede much. Wagon mines are closing daily not to open again, under present circumstances, and it is believed that many properties producing low-grade coal soon will follow suit. Operators insist that any marked reduction in prices necessarily will compel closing of mines under the present high cost of labor. But surplus stocks of coal are not so heavy as generally believed, they hold, and no overproduction of high-grade coal is imminent.

Order books of the iron and steel industry of the lower lakes region, probably the largest single consumer of coal, are fast filling with domestic orders, which are being solicited, and shipments to these plants are continuing uninterrupted.

Retail dealers claim to be unable to buy the grades they now require at a figure under the maximum. Supplies are so plentiful for the domestic trade that customers are refusing to accept "dirty" coal, of a kind they were eagerly seeking six weeks ago. To market ¾-in. lump bituminous has become a difficult matter, and retailers now are calling upon operators for—and are getting—1¼-in. lump. Quality and not quantity has become the watchword in the domestic trade. Domestic consumption has been reduced markedly by unusually mild weather, while the saving through a four-week ban on theaters, churches, schools and public gatherings is noticeable.

Influenza is on the wane in eastern and southern Ohio, resulting in improved labor and car-supply conditions. Shipments by members of the Pittsburgh Vein Operators' Association of Ohio in the week ended Oct. 31 totalled 8069 cars, compared with 4882 cars the first week previous, 5419 the second and 6103 the third.

Anthracite—Receipts have dwindled, and practically no market exists. The few cars of No. 1 buckwheat that filter through are hard to dispose of.

Lake Trade—The 2,300,000 tons of bituminous required by the Northwest to round out its quota of 28,000,000 tons will be floated by Nov. 23 without doubt. Loadings so far this month have proceeded at the rate of about 850,000 tons a week. After Nov. 23 special arrangements must be made with the Ore and Coal Exchange, Cleveland, for use of docks at both ends of the route. Duluth and Superior docks are reported filled, with labor restive and boats given slow treatment. Lake shippers in general are agreed that the pool of coal and vessel capacity this season has proved an unqualified success, and it is one war measure that both vessel interests and coal shippers hope will outlive the war. The Ore and Coal Exchange's revised and final statement shows that in October Lake Erie docks dumped 4,855,069 tons of cargo coal and 188,818 tons of vessel fuel, making a total tonnage of 5,043,887 for the month—a new high record. For the season to Nov. 1 the docks dumped 25,611,126 tons of cargo coal and 1,117,597 tons of vessel fuel, making a grand total of 26,728,723 tons.

DETROIT

Buying orders are fewer in both the steam and domestic branches of the coal trade in Detroit. Anthracite is not plentiful. Lake shipments are near the close.

Bituminous—There is a more conservative spirit apparent in the buying by users of steam coal and, also, on the part of retailers in the Detroit market. Neither class of buyers is displaying the interest and expressing the strong demands that were recently features of the local business. Instead, there is a general slowing down, and jobbers complain that they are meeting with considerable difficulty in hunting out buyers.

They believe the market has been surfeited with coal from Indiana and Illinois, sale of which was expedited by recommendations of the Federal and State fuel administrations that buyers should assure a supply by taking any kind of coal that could be had. Manufacturing plants with storage space have set aside large reserves. Quite a number of them appear to have concluded their buying was overdone, and they are now shutting off on orders and using coal from their stockpiles.

Retailers who had stocked up heavily with anything in sight are not finding the relief they had expected domestic buyers to provide. The latter are proving somewhat critical. Weather conditions have not been sufficiently severe to create a strong demand from householders, and those who are in the market show a disinclination to take mine-run and coal from Indiana and Illinois, with which they are not familiar. Some of the coal from those states is reported unsold on tracks.

Anthracite—With only a small amount of anthracite in hands of local dealers, shipments are being held at a smaller volume than in October. The allowance of two tons first fixed as the maximum for owners of baseburners is to be increased to four tons, when additional supplies are available, according to announcement by the state fuel administrator.

Lake Trade—Quite an easing off in lake shipments is now under way, this condition reflecting a general suspension of lake shipments, which is expected to occur about Nov. 23. Movement of coal to loading docks is in smaller quantity than last month. Some of the vessels chartered in the coal trade are finding it necessary to go to two or more docks to complete loading and avoid delays in port.

COLUMBUS

Continued weakness is shown in mine-run and screenings in the Ohio trade. There is still a good demand for lump and other prepared sizes. The stopping of the war has caused a lull in the general demand for fuel.

The chief feature of the coal trade in Ohio is the weakness in the mine-run and screenings markets, which are badly overstocked. This is due largely to the stoppage of mine-run shipments to the Northwest and the cessation of orders because of the ending of hostilities. While prices have not been cut to any degree, still there are cases where the smaller operators have been shading quotations in order to get rid of stock on hand. The domestic sizes are in good demand although the warm weather has hindered the retail business. The tone of the trade is not so good as formerly.

Some mines in the Hocking Valley section have been closed because of the lull in mine-run, as many are not equipped to screen the coal. Others have been closed down by the Federal authorities in their campaign for clean coal. But despite the influenza epidemic and the lack of orders, production is still fairly good. In the Hocking Valley the output is estimated at 65 per cent. and in Cambridge and Crooksville about the same. Eastern Ohio is having a pretty fair car supply and the output has been about 70 per cent. of the average.

Domestic business is rather slow as the war weather has curtailed orders from consumers. Stocks in the hands of dealers are large. Mine-run is stocked pretty heavily, but dealers are not buying that grade. Considerable West Virginia coal is now on the market and dealers are stocking splints and New River. Pocahontas is entirely out of the market and the same is true of anthracite. Retail prices are firm at former levels, eliminating the jobbers' commission. Thick-vein Hocking has the preference over thin-vein grades.

Railroads are taking a good tonnage of steam grades, which helps to relieve the situation to a certain extent. Manufacturing plants have stocks to last from four weeks to four months and even longer, and there is not much demand under present unsettled conditions. The fact that the ban is raised on certain nonessential industries is expected to stimulate the steam trade.

The lake trade is still active, although it is getting close to the end of the season. It is understood that the last cargoes will leave the lower lake ports Nov. 23. This time may be extended. The strike in the upper lake ports has not affected the lake trade in Ohio to any great degree.

Prices for short tons at the mines in the Ohio districts are:

	Mine-Run	Prepared	Slack
Hocking thick vein..	$2.50	$2.75	$2.25
Hocking thin vein..	2.90	3.15	2.65
Pomeroy Bend	2.50	2.75	2.25
Eastern Ohio	2.35	2.60	2.35

CINCINNATI

Continued limited production matches comparatively quiet demand. Transportation and labor conditions improving.

With the effects of the influenza epidemic still in evidence in the mining districts, according to reports received from several quarters, and with the lay-off which occurred on Nov. 11 on account of the general celebration of the cessation of hostilities, production of coal has not been at a high level. It has, however, kept pace with the current demand, which remains comparatively dull, except for occasional active spots.

There is in evidence something of a spirit of caution among manufacturers on account of the uncertainty of conditions following peace, but as a rule the trade does not anticipate that this will affect the demand for fuel to any considerable degree. The fact that coal will be needed for heating purposes and for all ordinary industrial operations almost without reference to the immediate effect of peace is generally taken to mean that demand will be at a normal rate, if not more so.

At the same time it is conceded that some of the extraordinary industrial activity which has been the direct results of enormous demands for war materials of various sorts will stop short, and that to this extent there may be a reduced demand for fuel. An easy market is expected by some, to last for the entire winter, barring weather of a severity paralleling that of last season, which is entirely improbable. So far, in fact, the weather has been remarkably mild, keeping consumption of fuel for heating purposes down to a lower volume than for several years.

LOUISVILLE

With exception of good grades of eastern Kentucky block coal the entire market is draggy and dull.

Jobbers and producers are generally up in the air as a result of the continued dullness of the market, coupled with the warm spell of weather, and further softening since the armistice was signed. Domestic coal, excepting the best grades of eastern Kentucky, is not in demand and the retailer is merely stocking his yard and marking time. The steam demand has been bad enough for some weeks past, but news of the peace agreement resulted in a further check in demand, as numerous industrial concerns cannot see much business ahead of them at the present time.

The jobbers and producers are having sleepless nights trying to figure out how and where to unload coal on hand. Some coal is paying demurrage, and other coal is being sold at below the market in order to keep things moving. Cars are plentiful, and labor supplies have been somewhat better since the influenza epidemic broke, with the result that many mines are getting more production that they can well handle, especially as every market in the country appears to be well loaded.

The steam consumer is playing a waiting game, and buying only what he has to have, feeling confidence in his ability to secure all necessary coal at future dates. Being uncertain relative to how long his business may be active if based largely on war orders he cannot afford to lay in coal. Again, price cutting has shown the weakness of the coal man's hand, and many consumers have about decided that they will buy coal at their own price before the winter is over.

As a whole the general market is in a very unsettled and bordering upon a serious condition. If the public needed help last winter and this year, the coal man appears to be the one who needs help this year. A good cold snap will probably help domestic business materially, but the steam situation is hard to figure out.

BIRMINGHAM

Local demand for steam coal only moderate. Domestic market continues stiff, with a great deficiency in the supply. Improvement in production slow, mine workers showing little disposition to work regularly.

Reports from local brokers and distributing agencies indicate about an even balance now between the demand for steam coal and the supply with which to meet such requirements. The market is in a little healthier state in that fewer cancellations of bookings were requested the past week than during the previous like period. The heavy drain on the output of the mines occasioned by 100 per cent. deliveries still being exacted on railroad contracts (which seem to be the only class of consumers without any stock accumulation), in conjunction with the depleted production of the past few weeks, has about equalized the conditions of supply and demand in a market which was showing indications of softness.

The need for domestic coal appears as acute as ever and inquiries are strong and insistent for this grade of fuel. The records of the Jefferson County Fuel Administration show that over 100,000 tons of domestic coal has been stored in the county since Apr. 1, which far exceeds any previous advance provision for winter fuel. Local dealers have little coal on hand.

Labor conditions at the mines are far from satisfactory, great indifference being manifested toward regular and steady work. Peace demonstrations demoralized mine workers for several days and resulted in a heavy loss in the output of coal.. The output for the week ending Nov. 2 was 3437,557 net tons, or approximately 100,000 tons short of what should be produced by the labor engaged in this industry.

Coke

CONNELLSVILLE

Celebration further reduces output. Possibilities of market eventually declining below Government maximum prices. Consumers will seek concessions.

After several weeks of declining production of coke and shipping of raw coal in the Connellsville region, last week's celebration of the cessation of hostilities made further inroads on production and normal conditions may not be restored even this week. The steel industry confined its celebration almost entirely to the one day, Monday, and even on that day blast furnaces were kept going to an extent, so that the celebration curtailed coke production much more than coke consumption. While the Fuel Administration has been gathering statistics of stocks of coke at blast furnaces for some time, it is only within the past fortnight that any figures have been given out, and they show an average of about one week's coke in stock at furnaces. The stocks are so irregularly distributed that the recent curtailment in shipments is likely to cause some furnaces to bank for a few days.

For the longer future, the cessation of hostilities is likely to cause a decline in the coke market. During the recent curtailment in production on account of the influenza epidemic, which is now not much of a factor, some observers expressed the opinion that without the curtailment a softening of the market would have developed. Throughout the period of price control, to date, there has been practically no shading of the Fuel Administration's limit prices. This is now expected for the near future, and some consumers predict a decline of as much as $1.50, which would make furnace coke $4.50. Consumers will have a lever in negotiations, as there is the alternative of contracting for the first six months or the whole of 1919 or of buying from hand to mouth. It is held that while the set limits on coal are rather high, the limit price on coke is still higher, proportionately.

It is doubtful whether the Fuel Administration will set any minimum prices on coal and coke, although there is a possibility of the War Industries Board doing this in the case of pig iron and steel products. Its action might take the form of naming reduced maximum prices and allowing the producers to adopt the prices as minimum also, of their own volition, and the producers could probably work together. Coke producers have not in the past shown as much ability to work together as have iron and steel producers. Up to date, at any rate, the coke market remains quotable at the set limits: Furnace, $6; foundry, 72 hour selected, $7; crushed, over 3-in., $7.30; clean screenings, over ½-in., $5.50, per net ton at ovens. Foundry coke has been somewhat harder to sell of late, although there has been no shading, while the market for screenings is much reduced, there being better supplies of other kinds of domestic fuel at less cost.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Nov. 9 at 279,650 tons, a decrease of 14,215 tons, and raw coal shipped at 193,837 tons, a decrease of 22,400 tons.

Buffalo—The demand eases off along with that for soal, furnaces no longer finding it hard to keep up a supply. It looks as if the prices fixed by the Government would soon be quite high enough, after so long being too low for any jobber to handle. Fuel coke is also much easier and may give way to bituminous so far as that will answer the same purpose. Iron ore receipts decrease slowly, on account of the lateness of the season, being for the week **297,744 gross tons.**

Middle Western

GENERAL REVIEW

Market in a weak state. Operators fear that cancelling of war orders will wreak havoc for a while. Outlook for next year optimistic.

Opinion is expressed that there will be a sharp break in the market. The industries, even in this Middle West district, which have been engaged in filling war orders will find their orders either cancelled outright or curtailed to a minimum. This, of course, will force an additional tonnage of free coal on the market when the market is least able to absorb it.

The public have practically satisfied their requirements and manufacturers have enough coal on hand to last until Jan. 1, 1919. The railroads, apparently, are not interested in coal. Add to this grave situation the fact that hundreds of thousands of tons of coal formerly absorbed by "war industries" will be thrown on a market, weak almost to the point of panic, and you will have a fairly good idea of the problem facing the average coal operator.

Some operators believe the only way to avert, if such a thing is possible, the debacle in the coal market is to abolish the present zoning system, with its accompanying rules and regulations; but whether the abolition of the zones would help matters is a question worthy of grave consideration.

It is only the immediate future that worries the coal man. That conditions will gradually improve is the opinion of nearly all operators. This country will have to undertake a vast program of reconstruction work, and it is generally believed that once this work has begun the demand for coal will improve and strengthen, until the demand is as great as in 1916 and 1917. Some of the best informed men connected with the coal-producing industry maintain that the demand for coal for 1919 will be greater than ever before experienced.

CHICAGO

Mild weather still continuing, few orders are placed for steam or domestic coal. Steam coal being sold below Government maximum.

The mild weather still continues, and few orders for either steam or domestic coal are being received. The big users of steam coal are bending all their energies toward reducing their various storage piles. The reason for this is obvious, as an unprecedented number of fires have originated within the last three weeks in various storage piles placed about the city. The idea in the mind of the average purchasing agent is to burn his own storage pile underneath his boilers, rather than lose his coal or have his coal deteriorate through spontaneous combustion. This development has naturally kept a large number of Chicago coal users out of the market.

Steam coal can be purchased from practically all fields at a substantial reduction from the price set by the Government. The domestic situation continues dull, with little or no demand, and there is no change to be looked for until cold weather sets in.

MILWAUKEE

The coal situation is satisfactory as far as supply is concerned. Little fear of a fuel famine. Receipts by lake slowing up some.

In striking contrast with this period a year ago, there is little agitation in Milwaukee over the coal supply, and it seems to be the general opinion that there is no danger of a fuel famine during the coming winter. With the two-thirds supply clause affecting all anthracite orders of more than six tons, the general campaign of fuel saving, and the pleas of officials to substitute soft for hard coal, the administrators think it probable that all consumers who cannot burn anything but anthracite will be supplied in full. Deliveries are now on a more satisfactory basis, and the prevailing mild weather contributes to make the lot of the coal man more serene.

Prices continue on the schedule which has prevailed for weeks. The advance of $1.05 on anthracite mined since Nov. 1 will not be experienced here, as there is little chance that any of this coal will reach these parts. At best the quantity would be light.

Receipts of coal by lake are slowing up somewhat, and unless there is a spurt during the last half of November, the month's figures will be the lowest since the opening of navigation. Thus far this month 56,277 tons of anthracite and 102,742 tons of bituminous have been taken over the docks, making the season's record up to this writing 616,246 tons of the former and 3,253,871 tons of the latter. As against last year's record this shows a loss in anthracite receipts by lake of about 20 per cent. and about the same percentage of gain in bituminous. About a month of navigation remains. Rail receipts of hard coal continue fair and serve to help out the delivery situation, as the coal is transferred direct to wagons and trucks.

ST. LOUIS

Market is utterly demoralized on Standard coals. Many mines shut down on account of no business and nothing in sight. Mt. Olive market slowly but surely breaking and Carterville coal a drug on the local market. Steam and domestic both affected and no country business. Cars plentiful, transportation good and unusually mild weather.

The local situation continues a discouraging one for the coal trade. The weather at this time is milder than in most years, and there is absolutely no coal moving except what is being put in storage by the dealers at greatly reduced prices and the regular steam trade that has to have coal on account of having no great storage facilities.

The Standard market is utterly demoralized. Screenings are going at practically anything the buyer will offer, and this usually means about $1.50 to 1.60 on good coal. Two-inch lump coal is down to about $1.75 to $1.85 and hard to move at that. Not only is the domestic trade stopped, but the steam business has fallen off nearly altogether. Steam plants are using up their storage coal.

Many mines in the Standard field have been working only two or three days in the past week and now contemplate shutting down for one or two weeks straight. There is much dissatisfaction among the miners over this. The only mines that are working anywhere near full time are those working on railroad coal, and this tonnage has been shut off at some places in the past week, closing these mines down entirely. The influenza is letting up in the Standard field and miners are now returning to work, throwing an additional tonnage on the market.

In the Mt. Olive field conditions are not so bad as those in the Standard districts, but they are rapidly coming to it. Mt. Olive coal for the first time in over a year is selling at below the Government maximum for domestic sizes. The steam market is still holding fairly well on this, but it is by extremely hard work. The tonnage of railroad coal in this market still continues to move, but it is questionable as to how long it will continue.

The Henrietta mine at Worden is expected to shut down the coming week indefinitely on account of labor troubles and lack of market.

In the Carterville district the mines are beginning to show a surplus of domestic coal. No mines have been idle as yet on account of no orders, but some mines have had coal unbilled in the evenings.

There is no fear that this coal will go below the Government price, but it is going to be somewhat of a task, if this weather continues, to move all of this tonnage in the next week or two.

As far as the south is concerned, this coal is a drug on the market. St. Louis has more than it can use and the southern territory for the first time in many months has a chance to get some of this coal, but is gradually reporting that it is overloaded.

Car supply is plentiful, movement is good, and miners are returning to work here, as in the Standard field.

It is going to take good, cold weather to stimulate the southern Illinois market. There are no outside coals coming in and no demand for any. The retail market is holding fairly well except on Standard, which is suffering a cut of 50c. a ton.

The wholesale prices are, with the exceptions, as noted:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump...	$2.55@2.75	$2.55@2.75	$2.40@2.70
3x6-in. egg..	2.55@2.75	2.55@2.75	2.40@2.70
2x3-in. nut..	2.55@2.75	2.55@2.75	2.40@2.70
Washed:			
No. 1.....	3.05@3.20	3.05@3.20	.....
No. 2.....	3.05@3.20	3.05@3.20	.....
No. 3.....	3.05@3.20	3.05@3.20	.....
Mine Run...	2.35@2.50	2.35@2.50	2.20@2.30
Screenings...	2.17@2.32	2.17@1.32	1.50@1.60

Special preparation on Carterville is 10 cents extra.
Williamson & Franklin Co. rate is $1.10.
Other fields 95 cents.

COAL AGE

Volume 14 New York, November 28, 1918 Number 22

Strong Position of the Coal Industry

MOST war industries are flooded with men and with plants. The coal industry has managed to avoid that unfortunate fate. It consequently needs little *readjustment*, if we may use that more correct word in place of the word *reconstruction*, which is familiar to us all but somewhat misleading and unfortunate.

True, the 5000 wagon mines, snowbirds, team-track mines, or whatever they may be called, will probably, as in the past, quit work in the summer and do a small business in the winter. But even though not as active hereafter as in the war, they will be more active than they were before it started, because the motor truck will greatly extend their radius of action. The men in them and employed by them will go back to the farms from which they were drawn.

The fate of these little mines with their meager investment is not important. What is of moment is the great outstanding fact that none of the track mines, which number 3600, need to go out of business. It might easily have been different had the Fuel Administration allowed without restriction the opening of new mines.

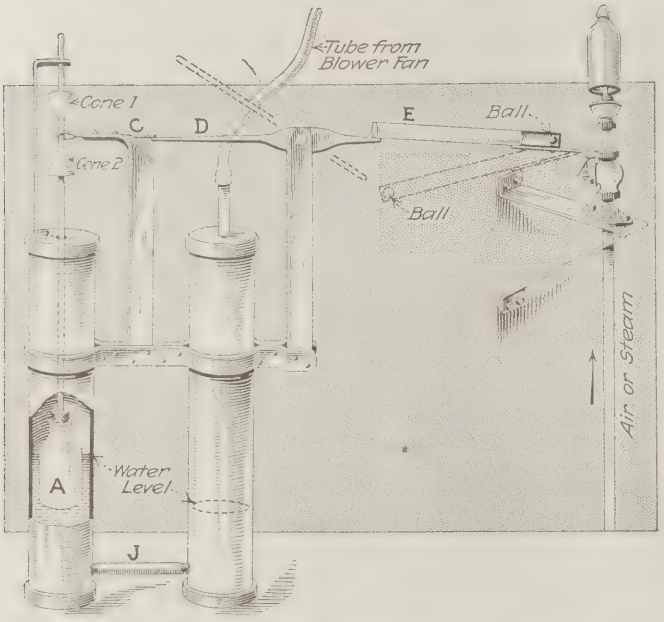
By its control the Fuel Administration was not seeking to protect the industry against the difficulties of the Readjustment Period. It had in mind solely the needs of the public during the war. New mines would have drawn off the men from old mines and would have set men to labor at work which would not have become productive during the war. It would have added to the number of mines when no more were needed. It would have consumed material for which the need elsewhere was great and would have hampered producing mines by transferring material from them to mines which were not producing, and might not produce during the war or even for some years thereafter.

The cry that new mines were needed was based on the fact that tonnage was not increasing as fast as desired. That would have been a valid reason for more mines had the shortage of mines and not the shortage of men to work in them and the shortage of equipment to operate them been the determining factors. Thus the Fuel Administration's action has prevented work on an increase in mine capacity which would have hampered us in winning the war and made much harder the winning of the peace.

The past labor shortage will prove a godsend to the miners. It is well that the nation got its increase in tonnage, not from an increase in the mining population, but from an increase in the activity of those engaged in mining. Let the mine workers take a lesson from this. The best way to avoid a glut of labor in an industry is to supply the demand by a readiness to work a full eight-hour day, if not more, whenever the pressure on the industry becomes severe. Then when slackness comes the ranks of labor will not be filled to overflowing.

The strength of the coal industry during the war was due largely to an excess of mines and men. The nation profited by this ill adjustment between industry and commerce. When commerce, owing to the war, made big demands on industry it was amply ready to supply what was needed as soon as a little propaganda work among the miners had been done.

But during peace this ill adjustment is regrettable, and one which we do not desire to maintain against the possibility of the "next war," which we fervently hope will never come. The industry should try to keep its men working steadily day by day, excluding holidays, for as many hours a day as is customary in other industries. It will be readily admitted that any less regular operation reflects on present-day finance, though it must be granted that to correct the condition might not only be difficult but likely to confront us with problems compared with which a little irregularity of employment might seem to be a light affliction.



IDEAS AND SUGGESTIONS

Alarm To Show Fan Trouble

BY W. F. DECKER
La Salle, Ill.

The illustration below shows an alarm that has been installed at the Mathiessen & Hegeler Zinc Co.'s coal mine at La Salle, Ill. This device has proved satisfactory in every way, and the idea may be valuable to others whose conditions approximate those encountered at the La Salle operation.

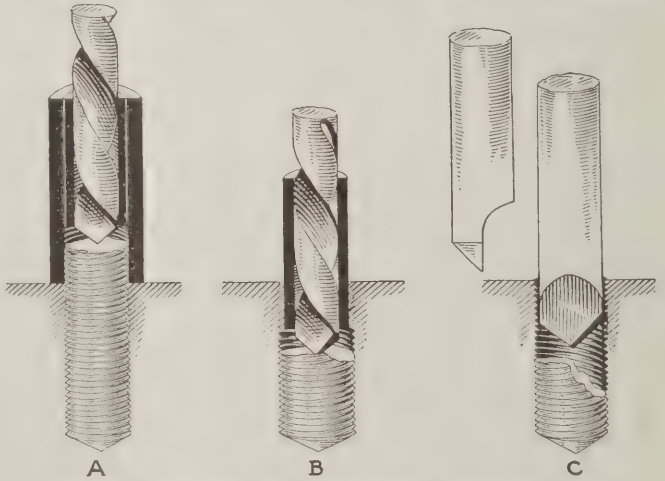
In this particular installation the motor driving the

DETAILS OF ALARM TO WARN OF FAN TROUBLE

fan derives its current from a line that also serves several other motors. The common source of energy is the main power plant of the company. In consequence, if the main circuit breaker goes out the fan motor as well as the other motors stop. Before the installation of this mechanical telltale the stoppage of the fan might not have been perceived until the regular rounds were made or word was received from the shaft bottom.

As may be seen from the diagram, the apparatus is simple and can be built by almost anyone. Two containers of equal size, or nearly so, are placed side by side and connected together near the bottom by the pipe *J*. Both containers are partly filled with water. The top of one container is connected to the pressure side of the fan while the top of the other is open to the atmosphere. A large water gage is thus formed.

On the water in the open leg of the device is placed the float *A* (in this case a tightly corked bottle), which carries a small rod that passes upward through suitable guides. Upon this rod are placed two cones, one pointing up and the other down. Between these cones and encircling the rod is placed the trip slide *C*, which is so arranged that an excessive movement of the cones either up or down will cause the rod *C* to move to the left. Such a movement of the rod *C* will trip the walking beam *D*, which will then rotate under the weight of the hollow lever *E*. The lever *E*, which is attached to the lever of the whistle, contains a steel or iron ball. When the tube is in normal position this ball rests against the end nearest the whistle. When the outer end of the lever is released from support and swings downward, the ball rolls to its outer end, thus bringing sufficient weight into action to blow the whistle, which is under 120 lb. air pressure.



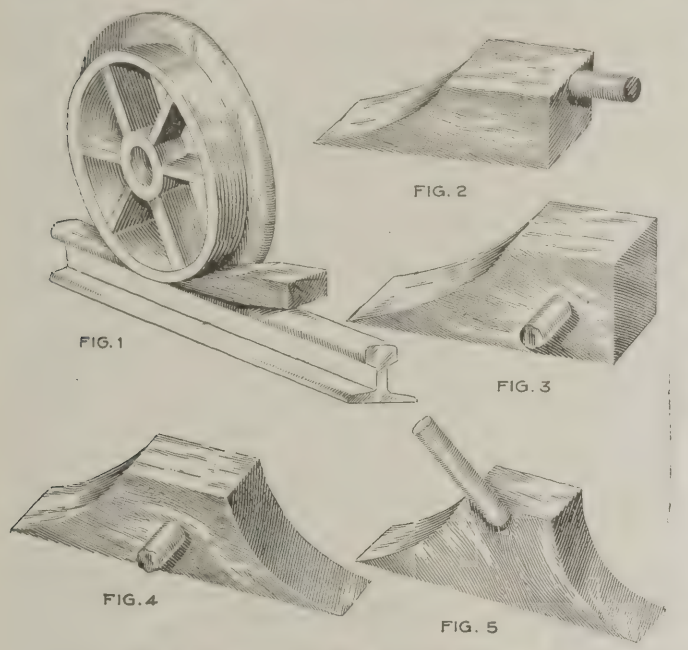
It will thus be apparent that so long as the fan runs at rated speed and the resistance of the mine is normal the surfaces of the water in the two containers will be at different heights, but practically steady, and the float *A* will support the cones at nearly a constant point. When for any reason, however, the fan stops or the resistance of the mine greatly decreases (as through short-circuiting of the air), the relative elevations of the water surfaces change. The float *A* will thus fall and the whistle will sound until the apparatus is reset.

Removing Broken Studs

BY ERNEST SCHWARTZ
Brooklyn, N. Y.

The extraction of a broken stud or cap screw is sometimes a difficult job. Many and varied have been the schemes adopted for this purpose. The accompanying illustration shows three similar methods that may be employed, as circumstances may dictate.

In the first instance the broken stud projects slightly



THREE METHODS OF REMOVING BROKEN STUDS

from the hole. In this case a tube the size of the stud is slipped over its end. This is provided with a bushing the internal diameter of which is the same size as the root of the stud threads. Through this bushing a drill of the same diameter is passed, the bushing acting as a guide. The stud may now be drilled out. If the stud is broken off within the hole, a bushing may be inserted directly as shown at *B*. This will

adequately protect the threads from the action of the drill. If a suitable bushing is not available, a special half-round drill of the same diameter as the tap drill may be made and used. The round portion will then bear against the threads without defacing them and thus guide the cutting end in its work.

Mine Car Chocks

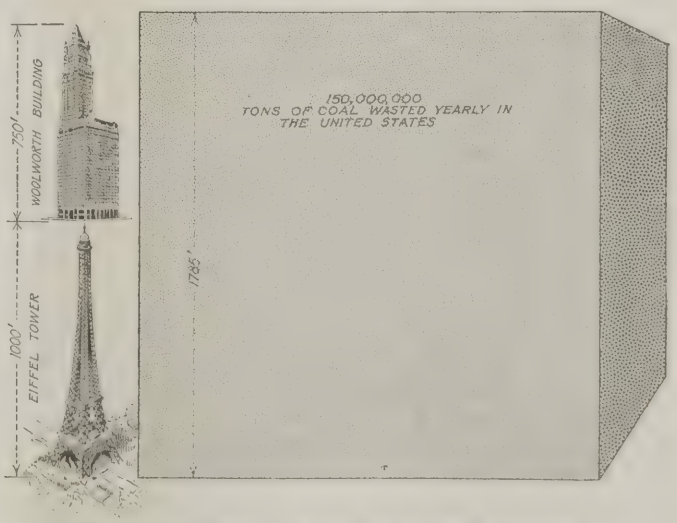
There are three general methods of retarding the movement of a car or holding it stationary—braking, spragging and chocking. Brake mechanisms are usually, but not always, incorporated in the car by the manufacturer. Many forms and types have been developed. Sprags are in many respects objectionable because of the severe stresses thrown by them upon the wheels, axles and running gear generally. They cannot be used with webbed wheels or those without spokes. Chocks do not stress the wheels and running gears nearly as strongly as do sprags; it is probable that their action is seldom if ever any more severe than that of brakes.

FIVE TYPES OF MINE CAR CHOCKS

The chock shown in Fig. 1 is practically a hardwood wedge. It has the advantages of being cheaply and easily constructed and may be used upon either side of the car. It has the disadvantage of bringing the hand close to the rail, where it is more liable to injury than if kept farther away. Furthermore, in order to place this chock properly, the one who uses it must get partially in front or under the side of the car, provided the car is built with overhanging sides, as is often the case in mine cars. In any case, the man who places this chock must take a stooping, squatting or kneeling position in close proximity to the car.

Fig. 2 is an improvement on the chock shown in Fig. 1, in that a handle is provided, thus almost entirely avoiding the liability of crushed fingers. This block is much thicker and thus has greater chocking effect. The chock shown in Fig. 3 is similar to that shown in Fig. 2 except that the handle is placed on the side. This chock, as shown, will function properly upon one side of the car only. Such chocks are often made and used in pairs. With a pair of them a car may be stopped from either side when moving in either direction. As a variation of this design a handle may be placed upon both sides. This makes the chock somewhat more clumsy to handle but renders it universal in application.

The chock shown in Fig. 4 is like that of Fig. 3 except that it is double-ended. One of these chocks may be applied from either side of a car moving in either direction.



With all of the foregoing chocks a man must stoop or kneel in order to place them in position. The chock shown in Fig. 5 is like that shown in Fig. 4, and has the same universal application, with the added advantage of a long sloping handle. This chock may thus be applied from a standing position and is therefore much more conducive to safety.

How Big Is 150,000,000 Tons of Coal?

By W. F. Schaphorst
Brooklyn, N. Y.

We have all been talking and writing glibly about the enormous amount of fuel wasted in the United States per year. Although this amount has been stated as 150,000,000 tons, nobody seems to be much impressed. In the hope that a visual quantity might have some effect, I sat down the other evening and "studied up" the average values and did some figuring. I learned that a short ton of bituminous coal occupies about 38 cu.ft. That being the case, it is a simple matter to multiply it by 150,000,000 tons, giving 5,700,000,000 cu.ft.

That looks like a big figure, but digits and ciphers in themselves don't express much unless we are familiar with their magnitude. Consequently, the best way to understand this figure is to extract the cube root. This gives 1785 ft. In other words, 150,000,000 tons of coal would make a 1785-ft. cube.

SHOWING PILE OF COAL WASTED YEARLY

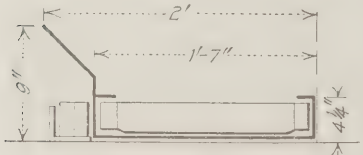
How much is 1785 ft.? The Eiffel tower in Paris is about 1000 ft. high. The Woolworth Building in New York is 750 ft. high. Put one on top of the other and you will "nearly" attain the height of this cube of waste coal. And remember that this wasted cube is just as wide and long as it is high. Isn't it a shame that we are wasting so much fuel?

Labor-Saving Methods and Appliances for Loading Coal

By G. W. ENGEL
Scranton, Penn.

SYNOPSIS — *A bibliography of the subject of machine loading in thin coal beds is here presented. Two types of machines appear to be particularly applicable. These and various methods of operation are discussed at some length, and interesting comparisons are made.*

THE purpose of this article is to show the present state of the art of mechanical loading in a general way, together with running notes from various technical publications. Thirty-two references to existing literature on this subject are made, giving the name of the article, its author, the publication in which it appears, the date, the number of words and succinct notes and drawings of many devices, concluding with original matter concerning two types of loaders that seem destined to a wide application in coal mines—The V-scraper, or scoop, and the conveyor.



The period of research and original work runs from 1905 to the latter half of 1918. It is evident to every mining engineer that a successful mechanical loader that will eliminate hand shoveling cannot but be beneficial through bringing under development great quantities of coal now unminable because occurring in thin beds. The matter is particularly important at this moment of ever-decreasing labor supply, because of war requirements, with corresponding imperative demands for increased production.

For thick coal beds there is now in successful operation in salt and coal mines a machine having a series of scoops or pans revolving about a shaft. The scoop digs into the coal and is elevated to a higher position, discharging its load onto a traveling conveyor which in turn delivers to the mine car.

For thin coal beds there are a number of appliances in more or less successful operation, such as buggies, conveyors, oscillating chutes, shallow cars or tubs, operated by wheel or drum and a wire rope; and V-shaped scrapers or scoops with open top and bottom, which are drawn along the bottom of the coal bed to the mine car. Some of these are covered by patents.

As to the V scraper and the conveyor, the latter has been in use many years both here and abroad. (See Arts. 6, 11, 26 and 33.) The V scraper (see Arts. 31, 32 and following paragraphs) was introduced in the anthracite region some four years ago under the direction of Superintendent William D. Owens, with the help and coöperation of George P. Gallagher, H. H. Otto, Thomas O'Brien, John Ridgley, Pierce Robinson and certain other Lehigh Valley Coal Co. men. Harry McKean Conner, at the suggestion of Eli T. Conner, worked up a scheme in detail for mining thin coal beds, in the early part of 1915, after having seen the Valley scraper. This scraper and method of operation requires more or less hand shoveling in order to load it with coal. To eliminate this hand shoveling there has been developed a somewhat modified form of scraper and method of operation. Superintendent Cadwallader Evans, Jr., and certain men under his supervision, introduced a change in the construction of the V scraper and the method of working it. This modified form of operation consisted in the placing of extra posts with attached open pulleys at the corners of the chamber face, and a wood pulley set some distance back from the face. This permitted the scraper to be loaded by drawing it across the chamber face, eliminating the hand shoveling.

Some of the larger coal companies are now operating the V scraper, and several others contemplate using this equipment for the purpose of mining very thin coal beds.

Section of Conveyor
FIG. 1

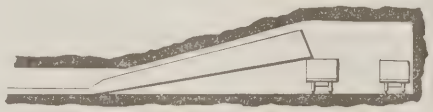


FIG. 2

FIG. 3

FIGS. 1 TO 3. CROSS-SECTION AND SIDE VIEWS OF A LOW DRAG CONVEYOR

Of the following articles, 32 represent the results of a research among the various technical publications of the world, and the others are the outcome of personal examination and original work.

1. Mechanical Coal Conveying at the Face.
Anonymous.

[Iron and Coal Trade Review.] Vol. 70, pp. 803-04, Mar. 17, 1905. 1800 w. Special reference to the Blackett coal conveyor at the works at Derwent Colliery, County Durham.

2. Mechanical Coal Conveying at the Face.
Anonymous.

[Colliery Guardian.] Vol. 89, p. 580, Apr. 7, 1905. 1300 w. Illustrated notes on the construction and management of an underground conveying system.

3. Working a Blackett Conveyor in the Working Face of a Thin Seam.
Badeley, H.

[Mines and Minerals.] Vol. 25, p. 607, July, 1905. Abstract of paper read before British National Association of Colliery Managers. The face is a right-handed one and has a dip of 1 to 16 against the loaded conveyor, which is 90 yd. long and built in 6-ft. sections. An 8-hp. electric motor drives the conveyor. Output increased from under 4 tons to over 10 tons per man. Seams not so advantageous to conveyors—undulating, tender roof, a roof very severe on

timber that would not allow the timber to be changed when shifting the conveyor over a bad lifting floor. From *Iron and Steel Trades Review*, Apr. 28, 1905.

4. The Mickley Conveyor.
Batey, J. W.

[Transactions, Institute of Mining Engineers.) Vol. 29, pp. 268-73, Apr. 8, 1905. (See par. 9.) The seam varies from 19 to 28 in. in thickness. Conveyor is a long shallow car, run by wheel and wire.

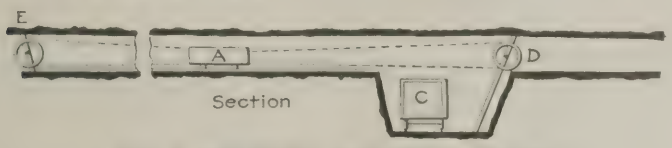

FIG. 4. MICKLEY CONVEYOR OR CAR

5. Use of Conveyors in Filling Coal Seams.
Blackett and Ware.

[Transactions, Institute of Mining Engineers.] Vol. 29, pp. 449-506, June 2, 1905.

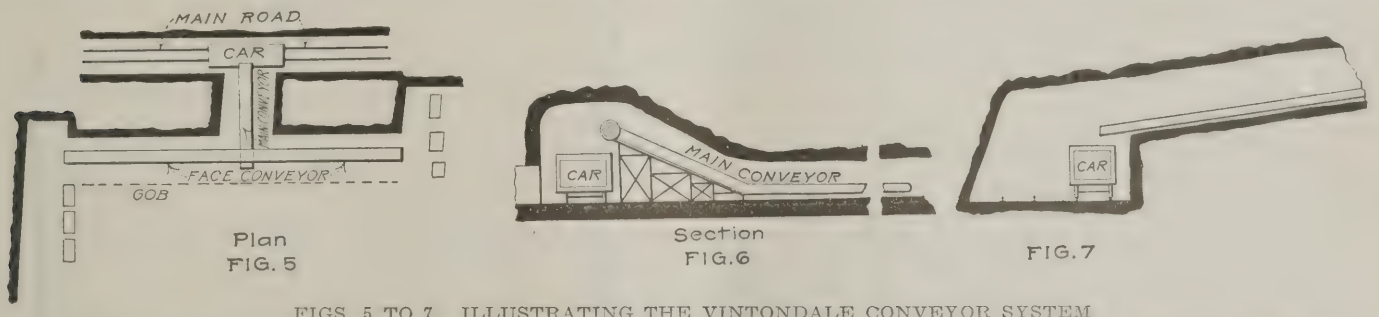
6. The Greaves Coal Face Conveyor.
Anonymous.

[Colliery Guardian.] Vol. 92, pp. 1073-74, Dec. 7, 1906. 1100 w. Description, with four illustrations, of a conveyor of the scraper type. The important points are the low loading level, the small space in which the empty or non-conveying chain is returned, practicability of using it in seams thinner than 2 ft., and its compactness and simplicity. By reference to Fig. 1, showing a section of the conveyor, it will be seen that it is only 9 in. high by 2 ft. wide. It will also be noticed that the loading side is only 4½ in. high. The higher, or 9 in., side farthest from the coal face protects the return chain. This return being on the side of the conveyor instead of the bottom tends toward reduced height, and makes it practical to operate the device in thin beds. Figs. 2 and 3 show the conveyor arranged for operation, while the roof or floor respectively are cut away to form the main road. The bed is represented as being 2 ft. thick, with the main road 9 ft. wide and 6 ft. high, which will give a good idea of the relative amount of headroom required when cutting top or bottom rock to get

8. A Conveyor for Filling Coal at the Face.
André, L.

[Transactions, Institute of Mining Engineers.] Vol. 31, pp. 106-8, Apr. 7, 1906. Used in seam 30 to 36 in. thick. Trough, requiring an oscillating movement.

9. The Mickley Conveyor.
Batey, J. W.



[Engineering and Mining Journal.] Vol. 81, pp. 652-53, Apr. 7, 1906. British Patent (1904) No. 16576, Sidney Bates. The conveyor *A*, Fig. 4, is a long shallow tub, 7 ft. long by 2 ft. 8 in. wide by 11 in. deep (but 7 in. deep on side next to coal face). Bottom of conveyor has two sliding doors which are slid open and coal falls into the car. Conveyor is run by a ¾-in. galvanized wire rope, fastened to each end. The rope is turned 1½ times around the driving wheel *D* and has a single turn on the return wheel *E*. The driving wheel is worked by hand. Gage of conveyor road 2 ft. 10 in., and is laid on iron sleepers. Coal seam, 19 to 28 in. thick.

10. Conveyor System for Loading at the Coal Face.
Parsons, F. W.

[Engineering and Mining Journal.] Vol. 83, pp. 958-59, May 18, 1907. 1500 w. Certain thin and dirty seams can be worked profitably by this method when other systems would result in loss. Abstract of paper read before Institute of Mining Engineers of Great Britain. Describes the Vintondale system (see par. 11). The conveyor is of the pan type, 12 in. wide at the bottom, 18 in. at the top and 6 in. high. In the pan is run a malleable drag chain. This chain passes over a sprocket wheel at the head end (which does the driving) and returns over another sprocket at the read end. Both front and rear ends are inclined—at the front to obtain height enough to allow the cars to pass under, and at the rear to allow for the sprocket wheel. An air engine drives the conveyor.

11. Mechanical Conveyors as Applied to Longwall Mining.
Thomas, J. I.

[Mines and Minerals.] Vol. 28, pp. 200-203, November, 1907. 3500 w. Describes methods and apparatus used at Vintondale, Penn., by the Vinton Colliery Company. Triple and single conveyor system. The article gives a detailed description of the inside plans and arrangement. The coal

FIGS. 5 TO 7. ILLUSTRATING THE VINTONDALE CONVEYOR SYSTEM
Fig. 5—Plan of Vintondale conveyor system. Fig. 6—Cross-section of Vintondale workings, showing delivery end of conveyor. Fig. 7—Swinging or bumping conveyor operated on a pitch

height for the car. This conveyor, working as it does in confined spaces, with the necessity of constant shifting as the coal is worked out, can be moved quickly and expeditiously without disturbing any of the standing timber or props.

7. The Mechanical Pit-Car Loader.
Anonymous.

[Mines and Minerals.] Vol. 28, pp. 185-6, November, 1907. Conditions under which it should work. Method of operating and arrangements necessary to get best results. The mechanical pit car loader, chamber and pillar, Hamilton Manufacturing Co., Columbus, Ohio. The loader is moved from place to place by its own power. Practical in large seams only, say 7 ft. One end of the loader sweeps the face forward and back, the coal going up on one side of the conveyor on the forward movement, and on the other side on the return movement. The coal is elevated to a position between the roof and gate end of the car, and then falls into the car.

worked is the Lower Kittanning seam, 42 in. thick, 8 per cent. pitch and 200 ft. of cover.

12. Maschinelle Fördereinnichtungen vor ort auf Rheinisch-Westfälischen Gruden.
Herr Forstmann.

[Glückauf.] Vol. 44, pp. 1281-90, Sept. 5, 1908. 500 w. Describes the conveying devices used in several of the mines of this district.

13. Underground Conveyors at the Kleinfontein Mine.
Way, E. J.

[Engineering and Mining Journal.] Vol. 86, pp. 715-16, Oct. 10, 1908. Trough conveyor. "Swing Conveyors at the Kleinfontein Mine, Transvaal-Rand District," by Edward J. May, Consulting Engineer, Hotel Savoy, London, England. Power drive impossible on account of the cost and mechanical difficulties due to conditions, so hand power by men pulling on upper end was used. Ore mine, pitch 26 deg. Conveyor 18 in. wide, 32 ft. to 224 ft. long, in 8-ft.

lengths; built of ⅜-in. iron and suspended from chains from the hanging wall. Time, 45 minutes to take down and put up again one 224-ft. conveyor. Number of holes for chains 29. Seventy conveyors are used, saving 420 men. Proposed to work out a monorail system which consists of a single rail suspended from the roof.

14. Swinging Chutes for Coal Mines.
Anonymous.
[Engineering and Mining Journal.] Vol. 87, pp. 362-63, Feb. 13, 1909. Swinging trough system. Dimensioned drawings; comparative costs. Swinging or oscillating

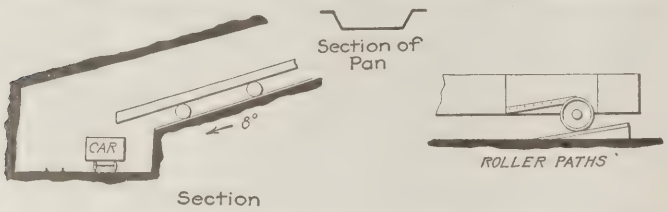


FIG. 8. SHAKING CONVEYOR HUNG ON ROLLERS

chutes for coal mines. By Lestelle & Hyve, engineers for the Compagnies des Mines de l'Escarpelli. Abstract from Bulletin de la Societé de l'Industrie Minerale, March, 1908. The system consists essentially of an iron trough suspended in such a way as to be free to swing, and subjected at the end of each swing to a jar which sends the coal forward and finally discharges it into a car standing in the entry. The swinging motion is given to the trough by a double lever, so bent as to be easily reached by the loader at the car. The jar at the end of each swing is given by a buffer fastened to the bottom of the lower end of the chute. The buffer and lever are adjustable. Pitch of coal seam 15 to 20 deg. No thickness of seam given. Chute from 20 to 100 ft. long.

15. Mining Coal with Machines in England.
Dixon, G. R.
[Engineering and Mining Journal.] Vol. 87, pp. 797-800, Apr. 17, 1909. Conveyor for handling coal in mine. Coal, 3 ft. 6 in. Coal is undercut by disk machine. No details as to the conveyor or undercutting machine. The article deals mainly with costs, arrangement of roads and plan of attacking the face on the longwall system. Detailed costs show that economy in mining results more from increasing value of coal produced (larger sizes) than from reduced working costs.

16. The Use of Coal-Cutting Machinery.
Rowland, R. H.
[Engineering and Mining Journal.] Vol. 90, pp. 1067-70, Nov. 26, 1910. Also notes on operation of conveyor used in longwall system; 12 to 150 ft. faces and two conveyors. Coal 3 ft. thick. Coal all cut by hand. Conclusion that conveyors in conjunction with reliable coal cutters should be a great improvement on the old method. Plans show the two 150-ft. faces and system of timbering.

17. A Coal Loading Machine.
Whaley, William.
[Mines and Minerals.] Vol. 31, pp. 206-08, November, 1910. 1500 w. Illustrated description of apparatus for use in mines to load coal cars. Developed by engineering firm of Meyers & Whaley, Knoxville, Tenn. Used by the United States Coal and Oil Company, Holden, W. Va. Seam 6½ ft. Rooms 36 ft. wide. Average coal loaded per day, 128 tons—six-day test; lowest, 90 tons (not enough coal); highest, 150 tons per day. Four men required to operate the machine—1 machine runner, 1 man in front and 2 men to handle cars and pick slate. Four rooms loaded out per day. The article gives plan and elevation of machine, also mine plan (7 rooms) and working face drawing. Machine built on the scoop shovel plan, the scoop going under the coal and throwing it back to a conveyor which in turn conveys the coal to the car.

18. Coal Face Conveyors.
Booth, A. E.
[Colliery Guardian.] Vol. 101, pp. 474-76, Mar. 10, 1911. 4000 w. Gives a general description of various types of and experience with the Blackett conveyor in thin-seam working.

19. Coal Face Conveyor.
Ridsdale, H. H.
[Iron and Coal Trade Review.] Vol. 83, pp. 1012-13, Dec. 22, 1911. 4000 w. Discusses the economical working of thin seams, describing types of conveyors and their use.

20. The Adair Face Conveyor.
Anonymous.
[Colliery Guardian.] Vol. 104, pp. 1011-12, Nov. 22, 1912. 2000 w. Drawing and description of a coal face conveyor designed to occupy as little space as possible in the vertical direction when discharging.

21. Moving Minerals in Thin Flat Beds.
Anonymous.
[Mines and Minerals.] Vol. 33, pp. 310-12, January, 1913. Swing chutes, scraper conveyors and shaking conveyors for transporting minerals underground. Page 310 shows a swinging chute suspended from the roof by chains. Ore is shoveled into the upper end and moved down by swinging the chute. Mention is made of the Vinton Colliery Co. conveyor. (See Art. 11.)

22. Machine Mining in Anthracite Mines.
Archibald, Hugh.
[Colliery Engineer.] Vol. 33, 471-76, April, 1913. 4000 w. Illustrates and describes methods of cutting and handling the coal that renders it possible to work thin seams profitably. Page 476 makes mention of the Delaware, Lackawanna & Western conveyor at the Dodge mine, by the panel longwall system. Rooms 24 to 40 ft. wide in 4-ft. seam. Coal goes by conveyor to small car on counter, thence by the counter and small car to the mine car on the gangway. Goodman, Sullivan and Jeffrey shortwall undercutting machines have been used; over 200 cars are produced per keg of powder. Five feet of bottom rock is taken up in gangway to give height for the car and topping. Top

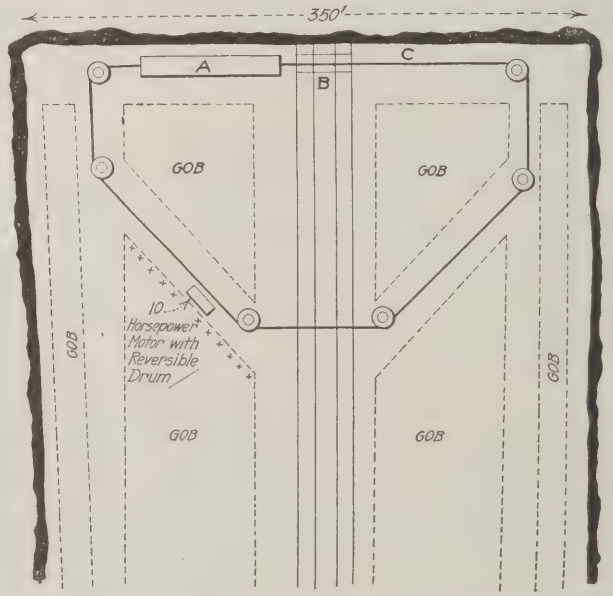

FIG. 9. A TRAVELING PAN CONVEYOR

of conveyor 12 in. from floor. Flat broad linked chain moves on the bottom of the conveyor trough, taking the coal over the sprocket wheel at the discharge end and travels back on angle iron guides under the trough. The driving motor and conveyor are built together.

23. Underground Conveying.
Mayor, Samuel.
[Colliery Guardian.] Vol. 105, pp. 1113-15, May 30, 1913. Serial, first part. Face conveying.

24. Nelson's Patent Longwall Coal Conveyor.
Futers, T. C.
[Colliery Guardian.] Vol. 105, p. 1013, May 16, 1913.

25. Mining with a Conveyor System.
Brown, J. F. K.

[Coal Age.] Vol. 8, pp. 204-07, Aug. 7, 1915. 4500 w. Mining safer; output increased; costs lowered. Conveyor has been in use for ten years. Vein 3 ft. 9 in. and coal 2 ft. 7 in. Dip 8 deg. Shaking conveyor is employed. The conveyor in use is of the old shaking type, and has been adapted from continental practice. The height from the floor to the edge of the pan is only 9 in. The width is 18 in. and the length 300 ft. The conveyor rocks back and forth on rollers, in specially arranged paths. These are so designed as to cause the machine to fall sharply at the end of the forward stroke, whereby the motion imparted to the coal is continued in the material itself, while the conveyor draws back for the next stroke—60 strokes per minute. The length is very important, varying as the grade. The theory is that of a shaking screen. Movable sides can be taken out and placed across the conveyor for the divergence of waste at any convenient point. The conveyor pan is in 6-ft. sections. The engine is driven by compressed air; 12 hp.; stroke, 5 in.; diameter of cylinder, 7 in.; weight of engine, 572 lb. Connection to the conveyor is through a lever action and rigid attachment, the cylinder at right angles to the line of the conveyor. (See Fig. 8.)

26. Longwall Conveyor and Loader for Thin Seams.
Dickson, James.

[Coal Age.] Vol. 7, pp. 368-9, Feb. 27, 1915. 1500 w. Describes a sectional conveyor and loader that is moved forward following the face. The cost of production has been reduced. *A* (Fig. 9) is conveyor with 6-ft. sections made of ¼-in. plate. Each section is 3 ft. wide and 9 in. high on gob side and open on the coal side. It is mounted on T-iron. *B* is a trestle under which the cars stand for loading. *C* is a rope for operating the conveyor. In actual operation the conveyor was drawn up until one end was close to the wheel on the end road, and the miners on that section were given 3 min. in which to load their coal, each section of conveyor holding 300 to 500 lb., so that with 20 sections there will be three to four tons on the conveyor. When ready to move, the man in charge signals the motorman to go ahead. The roof support was augumented by two rows of hardwood cogs between the conveyor and the gob, and built on loose dirt to facilitate their removal for use again.

27. American Coal Mine Haulage.
Anonymous.

[Colliery Guardian.] Vol. 112, pp. 61 to 63, July 14, 1916. 4500 w. Conditions and haulage systems, especially wire rope haulage.

28. Progress in Underground Ore Loading.
Richards, M. E.

[Canadian Mining Journal.] Vol. 37, pp. 344-46, July 15, 1916. 200 w. Types of loading machines.

29. Coal Face Conveyors Employed in the United Kingdom.
Walker, S. F.

[Coal Age.] Vol. 10, pp. 744-8, Nov. 4, 1916; pp. 790-4, Nov. 11, 1916. Exhaustion of the thicker coal beds in Britain has rendered the working of thinner measures highly desirable. To meet this condition the coal face conveyor has been developed. Two types of conveyor are described in this article.

30. Use of Face Conveyors.
Brown, J. F. K.

[Coal Age.] Vol. 11, p. 761, Apr. 28, 1917. Letter No. 1, from J. F. K. Brown, Montreal, Can. Reply to letter of Jim Golden and his nonsuccess with a face conveyor (Coal Age, Mar. 10, 1917, p. 445). Brown says that in one district alone on the continent of Europe, 40,000 ft. of conveyors are in operation under varying conditions of coal seams. He uses the Blackett conveyor. There are over 10 different types of conveyors, he says. In one case, to his knowledge, there were eight conveyor faces, each 300 ft. in length, seam 2 ft. 6 in. thick and 10 deg. pitch.

31. Scraper Mining for Low Veins.

[Employees' Magazine of the Lehigh Valley Coal Co.] April, 1916, p. 67. About 1350 words with three illustrations. This article tells about an economical method of mining thin flat seams of anthracite coal, devised by the Lackawanna Division of the Lehigh Valley Coal Co. "The mining of thin flat veins in the anthracite coal region has always been costly on account of the large amount of rock that must be mined with the coal. The time, money and energy spent on mining this dead rock and then piling it on huge rock banks on the surface is wasted. This same difficulty is met with in the coal regions the world over." * * * "Various systems have been tried and advocated, such as small buggies, chutes and low extensible conveyors, but a few months' or a half year's trial would reveal one

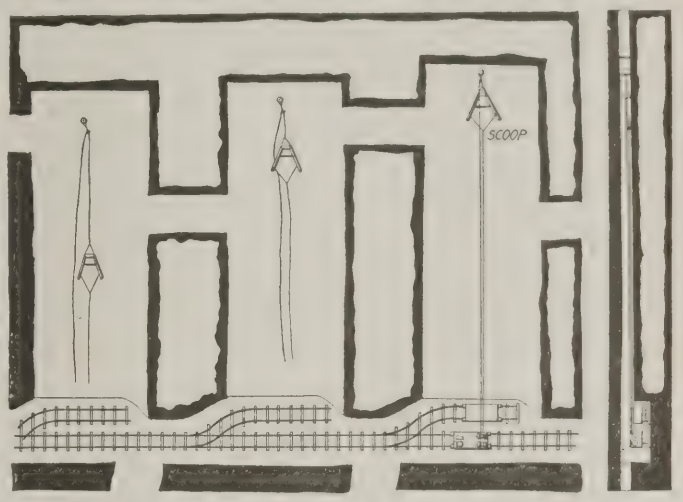

FIG. 10. PLAN AND SECTION SHOWING HOW SCOOP IS USED

weakness after another until they were proved impracticable."

A scoop for low veins has been built consisting of two legs of ⅛-in. sheet iron, about 4½ ft. long, properly shaped and fastened with heavy iron hinges to a small square back sheet about a foot wide. The two legs of the scraper swing open and close like the wings of a bird. To prevent the legs from opening too wide, a ⅜-in. chain about 8 ft. long is bolted to the ends of the wings. At the center of this chain is attached a ½-in. steel wire haulage rope, which drags along the whole device. A haulage rope is also attached to the back, so that the scraper can be pulled backward as well as forward. The scraper holds about 800 lb., and five scraperfuls will fill a mine car.

Operation—An eyebolt and pulley are driven in the roof, near the face of the chamber, and two pulleys fastened at the foot of the chamber, but close to the gangway rib. Of the last two pulleys one is used to guide the rope which pulls the scraper back up the chamber while the other guides the rope pulling the scraper and its load into the mine car standing on the gangway at the foot of the chamber. Opposite each chamber a double track must be provided, one for the mine car and one for a double drum electric haulage engine. A specially designed electric haulage locomotive with horizontal drums for dragging the scraper back and forth in the chambers has been employed. Fig. 10 is a plan and section showing how the scraper or scoop is used. The system of mining is the room-and-pillar, with rooms or chambers 24 ft. wide and 50 ft. from center to center of rooms. Of course, no rock is mined in the chambers, the only rock taken up is on the gangways. The coal is hand drilled and then shot off the solid.

32. Scraper Mining of Thin Bed Anthracite.
Humphrey, E. P.

[Coal Age.] P. 316, Aug. 15, 1918. About 6 columns, or 2750 words, with illustrations. Describes the scraper method and appliances for loading coal from a bed less than 3 ft. thick and pitching less than 20 deg. First introduced by the Lehigh Valley Coal Co. about four years before. The scraper is triangular in shape, open at the

top and bottom; 48 in. wide at the base and 14 in. high, made of No. 10 sheet steel, and when filled holds 8 cu.ft. of coal. It is either hinged at the apex or made solid in construction, depending upon whether the floor is irregular or smooth. The loaded scraper travels about 145 ft. per minute, and is filled at the chamber face by a man with a low lift shovel. The hoist used to drag the scraper up and down the chamber is a double drum machine, equipped with a 5-hp. motor and weighs 1650 lb. The drum has a capacity of 900 ft. of ⅝ in. wire rope used both for main and tail. This hoist is placed in an opening 5 ft. deep and 4 ft. high by 6 ft. long, on the opposite side of the gangway from the chamber. A new move and set-up of the hoist must be made for every chamber. At the face of the chamber the rope passes around a snatch block, which is secured to an adjustable screw jack with pointed ends. This jack is moved across the chamber as the scraping proceeds. Clearance for the car on the gangway is made by blasting up the bottom rock so that the top of the car is about on a level with the bottom of the coal in the chamber. This permits the scraper to discharge its contents directly into the car. The cars hold either 92 or 45 cu.ft. The gangway is 9 ft. wide and 4 ft. high on the low side. The chambers are from 24 to 50 ft. wide and vary in length from 100 to 360 ft.—200 ft. being the best practical length. The best loading record is 32 small cars per shift of 8 hours, with a night shift of two men and a day shift of four men, all doing "company work."

From the preceding references and quotations there stand out preëminently two types of machine for the getting of coal from the longwall or chamber face into the mine car—the conveyor with continuous carrying chain driven by gear wheel and pinion, discharging its contents into the car on the gangway road (see Arts. 6, 11 and 26) and the open top and bottom V scoop or scraper, drawn back and forth on the bottom of the coal bed by a wire rope, its contents dropped intermittently into the car on the successive forward moves, the empty scraper returning on the backward movement for a new load.

From present mining in Luzerne and Lackawanna counties there can be made a comparative study of the relative merits and performances of each of these two labor-saving machines, reduced to unit production of cars, tons or cubic feet per men per day.

Mine A employs the first, or conveyor, type of loader. The coal bed pitches from 2 to 5 deg., is from 18 to 27 in. thick, and is overlaid with hard sandstone and underlaid with a somewhat softer rock, which is blasted and removed on the gangways so as to get sufficient height for the car. The depth of the seam is about 150 ft. This will become 450 ft. as a maximum as the mining proceeds from the outcrop. The system of mining (see Fig. 11) is longwall advancing, except that from road 2, which is by chamber and pillar. The faces of the chambers off of road 2 are near the outcrop, and the pillars of coal are left to prevent the inflow of water which would take place if there were surface subsidence.

Two lines of pillars of coal are left to protect the main haulage roads in the longwall mining. (See roads 3, 3A, 4 and 4A.) The 150 x 250 ft. or upper panel between roads 3 and 2A has been mined and cogged. Road 3B is 7 ft. high and 12 ft. wide. Of this 7 ft. about 5 ft. of rock had to be blasted and removed from the bottom, thus permitting the top of the mine car to be a little lower than the bottom of the coal bed, allowing for a topping of 3 in. The cars standing on road 3B received the coal from the conveyor. The coal was drilled with jackhamers and shot off the solid. In this section the coal bed runs from 18 to 24 in. thick, so that it was impractical to use an undercutting machine. This required excessive blasting, which broke up the coal and kept the conveyor a considerable distance from the longwall face, reducing the prepared sizes and causing more labor through necessitating shoveling a considerable distance into the conveyor.

A slight increase in the thickness of the coal in the two lower panels between roads 4 and 3A makes it possible to use an undercutting chain machine. The seam here is about 27 in. thick, with a 6-in. band of bone and slate in the bottom. In this the undercut is made. Road 4B is 7 ft. high by 12 ft. wide. The mine cars are placed and loaded on this road. The two lower panels are each 150 x 150 ft., both being mined from the one road 4B. As the mining proceeds cogs are placed at about 25-ft. intervals. Of these two lower panels the left one is now being worked.

The number of men required to operate the upper

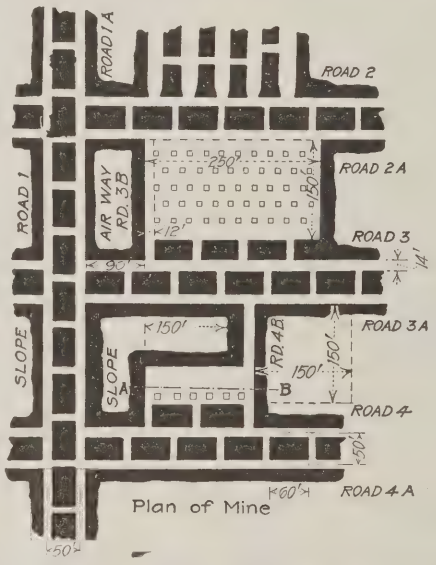

FIG. 11. TYPE OF MINING WHERE CONVEYOR IS EMPLOYED

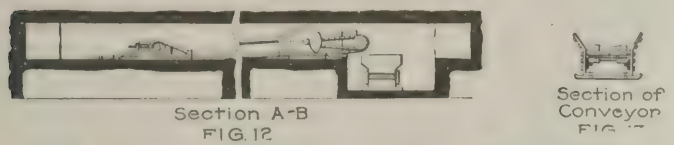


panel was as follows: One man in charge, 4 men drilling and blasting, 4 men shoveling coal into the conveyor, 1 man operating the conveyor motor and leveling the coal in the mine car on road 3B, making a total of 10 men. The number of men now operating the left-hand lower panel is as follows: One man in charge, 1 man operating the undercutting machine (machine runner), 1 helper (machine runner's helper), 5 men shoveling the coal into the conveyor, 1 man operating the conveyor motor and leveling the coal in the mine car on road 4B, 1 man drilling and blasting, a total of 10 men. Thus, it is noticed that there is required one man less for breaking down the coal in the lower panel than in the upper one, with a corresponding increase of one man for shoveling in the lower panel.

About two-thirds of the cog timber has been used before and comes from another coal bed where the mining of pillars is now in progress. There is little if any refuse in the seam, and material for pack walls or cogs must come from outside the mine.

The longwall chain conveyor, Fig. 13, is 12½ in. high by 20½ in. wide, the head end being 13 ft. long and 2 ft. high at the motor. It is driven by a 10-hp. direct-cur-

rent motor, operating at 950 r.p.m. The undercutting machine is of the ordinary chain type, 23½ in. high. Fig. 12 is a section of the seam showing the conveyor, the gangway and the car, the opening in the seam being 27 in. high.

The production per man per day of eight hours follows. This does not include the opening of road 4B or the mining of the first cut along section line *A—B*,

FIGS. 12 AND 13. SECTION OF COAL BED, SHOWING CONVEYOR AND GANGWAY

preparatory to the start of the undercutting machine and the placing of the conveyor.

In the month of August, 10 men, working 20 days each, produced 284 cars. The capacity of each car is 85.50 cu.ft., so that $\frac{284 \times 85.50}{10 \times 20} = 121.41$ cu.ft. per man per day, and $\frac{284}{200} = 1.42$, or the number of cars produced per man per day; 39½ cu.ft. of loose coal will produce 1 ton of prepared coal. Whence $\frac{121.41}{39.50} = 3.07$ tons of prepared coal per man per day.

Mine B, or the second illustration, uses the V scraper, mentioned in the introduction and shown in various figures. It is, however, a modification of the Valley scraper mentioned in Arts. 31 and 32. The seam varies in thickness from 18 to 36 in. and has an average thickness of 27 in. Jackhamer drills are used and the coal is shot off the solid. The system of mining is pillar and chamber. The chambers are driven on 50-ft. centers and are 30 ft. wide. A 7½-ton double-drum electric hoist is located in a crosscut between the heading and airway. (See *A*, Fig. 14.) From this location of the hoist five chambers are operated, two on the right, two on the left and one directly opposite. Two wire ropes, forming a loop, within which is the V scraper, pass over four 8 in. diameter pulleys in front of the hoist. Thence the rope goes along the gangway to two pulleys in front of the chamber at *B* and up the chamber. These pulleys are close to the rib and overhead.

The scraper, Fig. 16, holds about 12 cu.ft., and four scraperfuls will load a mine car. There is an iron brace at the front or wide end and a flange 3 in wide on the bottom of the scraper, tapered at the front to keep it from riding over the loose coal. Fig. 15 is a plan of part of a chamber face, while *A*, *B* and *C* are open pulleys, 6 in. in diameter, fastened to adjustable jacks, which are secured in the top and the bottom of the seam or opening. A passageway for the scraper is formed between the left rib and boards nailed to the bottom of a row of props some distance out in the chamber, as shown in the diagram.

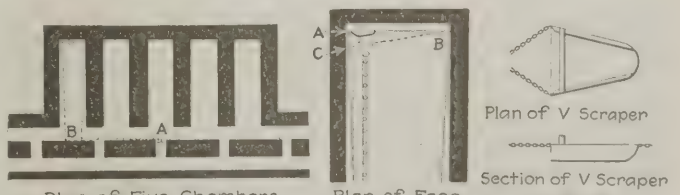
Suppose that the scraper has just returned empty, and is in the position shown by the dotted line. It continues its movement toward *B*, and when close to *B* is stopped. Then the rope is placed in the open pulley *C*, and the scraper pulled toward this point, gathering its load as it goes along. When close to *C* the rope is thrown off and the scraper is now in a position to pass and proceed down the chamber with its load. In order to scrape out the coal nearer the face, the open pulley at *A* is used. The method of operation between *B* and *A* is the same as that just described between *B* and *C*. Three men are necessary at the chamber face. By the proper manipulation of the jacks, the drum, the open pulleys and the rope, the coal can be scraped out of the chamber and shoveling eliminated, which, as must be agreed, is hard and laborious work in a thin coal seam.

The number of men required for the operation of the scraper is as follows: One man at *A* and *C*, Fig. 15; one man at *B*, Fig. 15; one man at the drum, called the scraper boss; one man on the gangway leveling the coal in the car; one man operating the electric hoist; four men drilling and blasting; total, nine men.

Covering the mining operations for one month, the average number of cars per man per day was 2.08 The capacity of the mine car is 42.61 cu.ft. Hence

Cu.ft. per man per day = 2.08 × 42.61 = 88.63.
Cars per man per day = 2.08, as stated above.
Tons per man per day = 88.63 divided by 3.95 = 2.24.

The number of cubic feet of loose coal per ton of prepared coal is the same as in Mine A.



In *Coal Age* of Aug. 15, 1918, p. 316, E. P. Humphrey states that the maximum production was 32 small cars per shift of 8 hours, with a force of 6 men, or 5⅓ cars per man per day. However, Mr. Humphrey informs me that a fair average production per man per day would be three cars of 45 cu.ft. capacity each, in a bed 36 in. thick, worked by pillar and chamber, with the coal hand-mined or shot off the solid. This would give the following results for the Lehigh Valley Coal Co.:

Cubic feet per man per day = 3 × 45 = 135;
Cars per man per day = 3, as above stated;
Tons per man per day = 135 divided by 39.5. = 3.42.

Comparisons may now be made with Mine A and Mine B, as follows:

	Mine A	Mine B
Cubic feet per man per day	121.41	88 63
Cars per man per day	1.42	2 08
Tons per man per day	3.07	2.24

Actual experience in Mine A proved that in the lower longwall panel, with an undercutting machine, the coal production was nearly double that in the uppen panel, where the coal was mined by hand. Thus if the Valley mine and Mine B should use the undercutting machine,

FIGS. 14 TO 16, SHOWING V-SCRAPER AND ITS OPERATION

they would nearly double production and a comparative table would show:

Name of Mine	No. of Men	Thickness of Seam	Production per Man per Day Cu. Ft.	Cars	Tons	System of Mining
Valley	6	36 in.	270.00	6.00	6.84	Pillar and chamber
Mine A	10	27 in.	121.41	1.42	3.07	Longwall advancing
Mine B	9	27 in.	177.26	4.16	4.48	Pillar and chamber

Longwall mining should also increase the production of Mine B and the Valley mine. However, for a fair comparative estimate it will be noticed that the Valley mine has the thickest coal bed, and only a few inches

more or less, when considering thin coal seams, sometimes makes all the difference between profitable or prohibitive mining. Also, in Mine B, the coal is far superior in quality, parting easily from roof and floor, being crisp, bright and sparkling; the table above is thus valuable as showing the advantages of using machine mining to increase output. Hence, a fair comparative table would show:

Name of Mine	No. of Men	Thickness of Seam	Production per Man per Day Cu.Ft.	Cars	Tons	System of Mining
Valley	6	36 in.	135.00	3.00	3.42	Pillar and chamber
Mine A	10	27 in.	121.41	1.42	3.07	Longwall advancing
Mine B	9	27 in.	88.63	2.08	2.24	Pillar and chamber

On the basis of cost, having regard only to the number of men required, the order of excellency would be: First, Valley mine; second, Mine B, and third, Mine A. Thus, it can be seen that the V scraper reduces the labor necessary in mining—the Valley mine requires four men less, and Mine B one man less. As to production, of course, merit should be given, first, to the Valley mine, with 3.42 tons; second, to Mine A, with 3.07 tons; third, to Mine B, with 2.24 tons per man per day.

Signaling in British Coal Mines Under the New Act

By Sydney F. Walker
Alexandria Park, Bath, England

A New Coal Mines Regulation Act was passed by the British Parliament in 1911, and subsequently special rules have been issued (in 1912 and 1913), some of which have an important bearing upon the matter of signaling. With shaft signals, for instance, a new requirement is made. Under the old rules a sound signal that could be heard by both engine man and top cager was sufficient. Under the new rules a visual signal must also be given. This must be placed in such a position that the engine man can always see it without turning his head, and the last signal must remain visible until the engineer has completed the order implied by the signal.

Where men are carried on the cage a difficulty in complying with this regulation arises. Under both old and new rules, one rap always means that the hoist man is to commence the wind. When men were to come up, a special signal was made under the old rules; three raps in some districts, four in others. It has always been forbidden to carry anything in one cage, except men, when men were riding in the other. Thus the top cager had always to give permission for men to come up by replying to the bottom cager's signal. Men were then allowed to go on the cage.

It was often difficult to obtain a top cager's permission to send men up during the ordinary working hours, because it meant the loss of two complete hoists of coal. When men were coming up, under the old rules the bottom man signaled to the top cager and to the engineer by one operation, then waited until the top cager returned the signal. When men were to be allowed to come up, the top cager so signaled to the bottom man and to the engineer. The men then got onto the cage at the bottom, and the usual signal to commence the hoist was given. Under the new rules the engine man must have something before him, from the time the men are signaled to come up until he commences the hoist.

Under the old rules there were two kinds of signal employed, mechanical and electrical. With both there was a bell in the hoist house that was struck from one to four times, according to the signal to be given. With some forms of mechanical signal there was a dial, over which a hand moved, the number to which it pointed corresponding to the number of raps given. Thus when 3 was signaled for men, the hand first moved over the dial to that figure, and when the signal was given to commence to wind, it moved on to the figure 4. Under the new rules this arrangement is not sufficient; if 3 means men riding, 3 must remain in sight of the hoist man, undisturbed by subsequent signals, until the hoist commences.

With the electric method of signaling, which was not employed at many mines, there was no visual signal at all. There was usually a bell on the tipple, as well as one in the engine house, and both rang simultaneously when the bottom cager signaled, the required number of strokes being sounded on both bells at the same time.

Two methods have been proposed and, I understand, adopted to a certain extent, to overcome the foregoing difficulties. The chief obstacle to be surmounted is that the signals must not be cumulative. The signal announcing men must not be interfered with. In one system of electric signals the visual sign has been obtained by copying the mechanical dial, the iron core of a solenoid electro magnet taking the place of the pull wire, the hand or pointer being moved round the dial by a ratchet and pawl.

To meet the new requirements there are two concentric dials and two ratchets. The pointer sweeps over the inner dial and a flag, carrying the word "Men," is carried round by the second ratchet and appears behind the clear glass space corresponding to 3 or 4 gongs. The outer dial is merely employed for calling the hoist man's attention to special signals. The pointer and flag work independently of each other, the flag being set in motion only when men are to be carried. At the pit bottom there are two pushes, or contact makers; one is used for giving the signal on the bell and for moving the pointer over the dial; the other is used only when men are to come up.

The firm that is introducing this apparatus has also worked out a mechanical signal on similar lines. It has two dials, a pointer and the flag with "Men" upon it appearing behind the clear glass space. The bell, however, is worked by one pull wire and the flag mechanism by another.

In the other apparatus that has been developed electricity is employed exclusively, and the arrangement is practically an extension to mining work of the indicator system employed in houses, hotels, etc. The indicators consist of panels of glass, behind which incandescent electric lamps are lighted when a signal is given. A screen appears at the same time, on which the signal transmitted is shown in clear lettering. In the engine house there is a panel indicator, having one panel for each signal that can be given, or alternatively, a limited number of panels, portions of each panel corresponding to each signal. There are two bells in the engine house: one may be rung from the tipple, and the other from the pit bottom. The electric lamps are energized either from a small battery of accumulators, a battery of

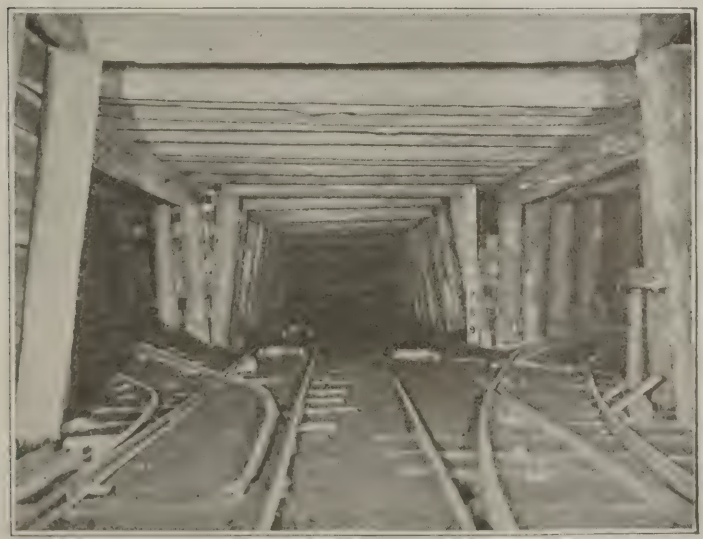
New Mine at Cassidy's, British Columbia

When the Granby Consolidated Mining and Smelting Co. acquired coal rights at Cassidy's, Vancouver Island, B. C., a short distance south of the City of Nanaimo, it was stated that it would have a producing mine in operation within a year. There was some speculation at the time as to whether, in view of the general shortage of labor and the difficulty, comparatively speaking, of obtaining machinery, it would be possible to accomplish this. The question now is settled. The company has reached the goal set. Its new colliery is in operation, a thoroughly modern plant having been installed, through which there passes every month an average of 2700



POWER HOUSE AND TEMPORARY TIPPLE OF NEW MINE IS SHOWN ON LEFT. THE RIGHT VIEW SHOWS THE 12-FT. OUTCROP OF THE DOUGLAS SEAM

tons. That this production will be increased materially in a short time there is no doubt, as development work is being advanced with a view to putting the mine in the front rank among those of the Island in regard to output.

The work of opening this new mine was commenced late in 1917. All that had been done up to that time was the demonstration by means of drilling that there was sufficient coal within the area controlled by the company to warrant the expenditure contemplated. A townsite had to be laid out, the land cleared, buildings constructed for the housing of plant and bungalows built for the accommodation of employees. All this was done and now the work is practically completed. At the same time the mine work was advanced with the utmost vigor. Three slopes were driven—one the meanway, one for haulage and one the airway. At the face of the manway, at a depth of 196 ft., the coal was 11 ft. in thickness and, from reports, has continued at about this thickness up to the present. The coal is of good quality.

LEFT—MAIN HOISTING SLOPE AND ENTRANCE TO NO. 1 SOUTH AND NO. 1 NORTH LEVELS. RIGHT—FACE OF NO. 1 SOUTH LEVEL, SHOWING TEN FEET OF COAL IN THE DOUGLAS SEAM

A level was driven to the right at a point 175 ft. down to connect with the other two slopes driven from the surface. This was driven in a seam running between 10 and 11 ft., so that the three slopes are in a good substantial seam of coal.

At the start a temporary tipple was used, but the main tipple structure now is underway and should be ready for use soon. A large brick smokestack has been constructed and two 250-hp. boilers as well as two Stirling water-tube boilers are being installed. There also is a modern pumping plant, while a sawmill has been erected capable of turning out 12,000 ft. a day.

To provide storage for railroad cars a long siding of standard gage has been constructed to parallel the Esquimalt & Nanaimo Ry. From this spur a standard gage railway has been built approximately one mile in length to the mine site. At the end of this spur is the mine yard trackage. George Fraser, a mining man of experience and ability who is well-known in British Columbia, is the general superintendent.

It is the intention of the Granby Consolidated Mining and Smelting Co. to use the greater part of the coal from its Island mine for the making of coke, modern by-product ovens for which purpose are in process of construction at Anyox, B. C., the company's coast mining and smelting center. These ovens, it is reported, will be ready in the course of a few months. Work on them is being pushed forward as rapidly as possible.

Complete Gasification of Coal

By M. Meredith
Liverpool, England

In view of the atmosphere of controversy which at present surrounds the problem of carbonization, and particularly the future methods to be employed, it is interesting to refer to endeavors which are being made in the direction of the complete gasification of coal and coke in one operation. It is generally known that if a ton of coal is treated in special equipment for the purpose it may, apart from the ash it contains, be converted entirely into gas, of which product it will yield some 65,000 cu.ft., having a calorific power of about 375 B.t.u. per cubic foot. The "double-gas" plant for this purpose is the invention of an Englishman, and particulars are now at hand of an equipment which is being employed for the same purpose in Germany, and which is made by the well known Dellwik water-gas company of Frankfort.

The apparatus possesses some novel features, but consists in the main of a producer, the lower portion of which is divided into two halves by a curtain wall. Coal is fed into the upper portion and is converted into coke before reaching the divided chamber. The process is similar to that employed with the ordinary type of water-gas plant, in that air and gas are admitted at intermittent periods. In this case, however, a superheated supply of air is utilized, and by this means the fuel in the coke chambers is raised to a temperature of 1400 deg. C., the producer gas being taken off at a point which corresponds with the zone where the coal is completely changed into coke.

During the gas-making period a gas outlet is opened above the coal bed, superheated steam is admitted to the base of the producer, and the water-gas thus produced rises through the coke and passes upward through the entire column of coal. This water-gas at the time of its formation is at a temperature of some 1300 deg. C. and provides the greater part of the heat for the carbonization of the coal, the gases from which are swept from the producer and carried through subsequent equipment of the ordinary type for the removal of sulphuretted hydrogen, tar and ammonia. Condensation is largely effected in the upper layers of the coal bed so that the gas leaves the producer outlet at a temperature of only some 200 deg. C. The producer gas yielded during the blowing period is not wasted, but is utilized for superheating the steam for gas-making.

The duration of the intermittent periods of blowing and gas-making varies in accordance with the kind of coal employed, but generally speaking the "blow" continues for from one to three minutes, while gas-making may be carried on for from five to ten minutes. It is found that by employing an excess of steam a maximum of ammonia is obtained.

An unsatisfactory feature of the process, a feature which is absent from the English system, is the necessity for admitting a certain quantity of air during gas-making. It is said that the quantity of heat demanded for the coking of the coal is greater than that which can be supplied from the stream of water-gas, and hence the necessity for introducing air; but it seems that by modifications in the working it is possible to produce a gas of moderately high calorific power or one of lower quality. When a comparatively good coal is employed the final mixture of gases obtained contains 50 per cent. of hydrogen, 10 per cent. of methane, 30 per cent. of carbon monoxide and 1 per cent. of unsaturated hydrocarbons. The calculated calorific power of such a gas is 384 B.t.u. per cubic foot.

Legal Department

Damages for Wrongful Discharge — An employee wrongfully discharged under a contract engaging his services for a definite term is entitled to recover salary for the unexpired portion of the contract term, less earnings in other employment during that time. (Texas Court of Civil Appeals, Consumers' Lignite Co. vs. James, 204 Southwestern Reporter, 719.)

Liability on Coal Dealer's Bond—Under a bond given by a wholesale dealer to secure compliance on his part with a contract for the purchase of fuel, including a provision that he would make monthly settlement for deliveries, the selling coal-mining company was not bound to terminate the contract, nor to notify the surety, on failure of the dealer to make payments when due, and failure to do either does not preclude the company from enforcing the bond against the surety. (Alabama Supreme Court, Alabama Fuel and Iron Co. vs. Alabama Fidelity and Casualty Co., 79 Southern Reporter, 57.)

Defect in Coal-Handling Device.—Defendant, a company which constructed a coal-handling device for plaintiff's employer, a coal company, is not liable for injury sustained by plaintiff through defective construction by defendant of a guard rail forming part of the work, if there was no knowledge on defendant's part that the particular defect would prove to be imminently dangerous to life or limb. (Wisconsin Supreme Court, Miller vs. Mead-Morrison Co., 166 Northwestern Reporter, 315.)

Need of Efficiency in Coal Mining

By SPECIAL CORRESPONDENT

SYNOPSIS—*Many mines today are being operated by the antiquated methods of a generation or two ago. Old, obsolete, broken-down much-repaired machinery is in quite a few cases being employed to the distinct disadvantage of the owners. If cost of delays from such equipment was charged where it should be, the faulty machines would be promptly placed where they belong—on the scrap heap.*

RECENTLY I visited one of the oldest mining properties in West Virginia. This mine puts out about 800 tons of coal per day, and it only requires 14 men and one perfectly good mule to get the cars onto and off the dump. The tipple payroll amounts to barely $48.50 per shift, or only slightly over 6c. per ton of coal handled.

While this dumping cost (which does not include the mule's expenses) might rightly be considered as being "up to G," it is not so far above that of many mines as to be prominent through its isolation. It is high, yes, outrageously high, yet not higher than that at many another operation of similar character. Around even the average mine many leaks—in the shape of unnecessary daymen, for instance—may be found. Such needless drains in any well-organized business of some other nature would inevitably mean one of two things, either financial ruin or a new manager—possibly both.

It is no uncommon sight about coal mines to see a motorman using (or attempting to use) a locomotive that is either about half as heavy as it should be for the work in hand, or one that has long since "seen its best days" and been fit only for the scrap heap. When such a machine breaks down (as it does almost hourly) it blocks other motors that may possibly be in good condition, keeps coal off the tipple and lays the tipple gang—dumpers, trammers, weighmen, pickers, loaders, spotters—idle. Thus a totally unnecessary expense is added to the cost of each ton of output; and this increment of cost that ought never to have existed at all is invisible, as such, on the cost sheet.

The foreman is not infrequently compelled to remark, "Yes, that old piece of junk called a mining machine over in the fourth left burned out again today, and six men had to knock off." This machine has a record for doing this very thing, particularly when the pit boss wants to do a good day's work. Here is another case of trying to get service out of the unserviceable. This machine has been broken and repaired until it is a creditable monument to the ingenuity (I dare not say skill) of the repairman. As a matter of fact, it is a labyrinthine conglomeration of yokes, tie rods, braces, cunningly devised forgings, reinforcing plates, patch bolts and solder, with possibly a few hundred yards of insulating tape thrown in for good measure.

The condition of this mining machine has been brought repeatedly to the attention of the superintendent and master mechanic. They either believe that it is good policy to "worry along" or know that the machine in toto should be replaced, but have been prevented from procuring a new one by the man higher up. Such higher-ups often "steam-roller" a requisition for a new machine, yet readily O.K. a request covering repairs for some old obsolete contraption. They are firmly convinced of the villainy, ignorance and general depravity of the machine runner. If he continually breaks his old machine, why in the name of common sense should they pay out good money in buying a new machine for him to smash up?

Then there is the question of rolling stock. How many times have you seen a locomotive tug and pull and groan and grind and slip its drivers in an attempt to start a trip of cars that any healthy mule should be able to pull. Next time you see this give the wheels or boxes the "once-over" at close range. You will find dry journals or wheels that have long since eked out or ground out or spun out their normal existence and performed their intended duty or that for which they were designed. Usually such wheels will be found to be of the ancient plainbore type—and in poor condition at that.

Hard on the Third Commandment

The motorman may sand the rails and turn on the current; the triprider may grin; the pitboss may wax impatient; and the third commandment be strained far beyond its elastic limit or even smashed to smithereereens—yet the motor refuses to mote the cars to tipple. And back in the mine two or three or a dozen or more loaders wait (for a while) for the empties they should have received as soon as their last car was loaded. Fifteen minutes, twenty minutes, maybe half an hour they wait. Then they fill their pipes, light up and light out—for home. Out on the tipple the dump crew organizes itself into a board of naval strategy to determine why the German grand fleet did not come out from behind Heligoland while the war was on.

A few hard-running cars are burning up what is left of the locomotive, consuming untold energy, delaying the transportation system all the way from the working face to the tipple, while the high peak load caused by the stubborn journals keeps the power house man on

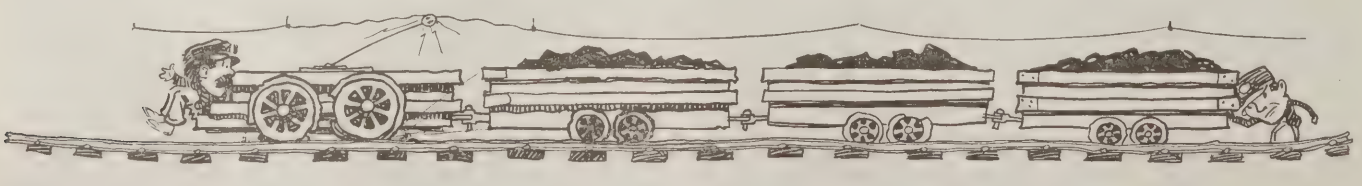
the jump putting in the circuit breaker. Every time the breaker goes out it means that everything on the circuit is deprived of "juice" and comes to a standstill until the breaker is put back in again.

Those old car wheels have dripped oil from the working face to the dump and back again times without number. The oiler is kept busy with a 1½ in. by 2-ft. gun, squirting black strap at or on (not always into) the journal boxes. The tipple floor reeks with it, is swamped with it, sometimes shoesole deep; and the dump crew (sometimes purposely, sometimes otherwise) slip and skid and slide and skate about as if in a sure-enough rink. Nobody can assign any good reason why oil should be smeared all over the lease when it ought to be employed in the car wheels. Application elsewhere is utterly unnecessary, as there are many types of wheels on the market so constructed as to confine the lubricant where it is needed—against the wearing surface.

In many mines one storage battery would do the work of six or seven mules and an equal number of skinners. One motorman and one triprider would replace the whole gang. In spite of this, however, the Missouri locomotive is still doing duty (that is, after a fashion), still getting crippled, still eating good hay and grain and other food whether he works or not, when he might be replaced by steel and iron and copper and lead and chemicals, etc., at a great saving. Of course, some mines cannot profitably displace mules with storage-battery motors, but most mines can do so to advantage. There is a mighty good way to solve this question, however, and every operator should *know* what is the cheapest method of handling his output.

How much money is wasted annually by coal men in lubricants because they have not taken the trouble to find out or demonstrate just what kind of grease or oil they should use upon each type of machine? And how many machines are damaged yearly by having the wrong kind of lubricant applied to their bearings?

A friend of mine has several barrels of a certain lubricant that he purchased for a particular purpose without ascertaining if it was the proper kind to use. After he had bought this and had it delivered and stored away in his warehouse, the maker of the machine upon which he intended to use the grease came along and told him that if he used this particular grease his machine would be in the shop in less than a month. Foolishness? Yes. Carelessness? Assuredly. Still this is an existing case, and many such could be found if all the men who had made similar purchases were frank enough to own up to them and admit the facts.



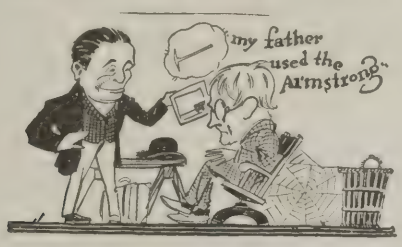
Of all business men under the sun, the coal operators are perhaps the ones most thoroughly tied, bound, manacled, straight-jacketed, lashed and cobwebbed to precedent. Many of them appear utterly incapable of standing on their own feet and deciding for themselves. They must do as the other fellow does, or as those have done who have preceded them. This propensity has caused coal men to lose many dollars. For instance, a man bought a certain kind of equipment. It was practically untried, and there appeared to be every reason in the world why it should be a failure. Nevertheless his friend bought the same equipment because the first man did. It did prove a failure, and they both lost heavily by the deal.

The other day I was talking to a man who has been operating mines for twenty years, and he asked me about a certain widely advertised mine appliance, one that has stood the gaff of practical, hard service for years, but not in this man's section of the country. He told me he would like to buy this equipment, but he did not know what his men would think about it. It was a new appliance in his field and he believed he would wait awhile. This device would undoubtedly have proved a money saver, and his men would have welcomed it, but the operator had to take a step by himself not in accordance with precedent. No other man near him was using this particular equipment and he was afraid to trust to his own judgment.

In any other business now existing that is one-fiftieth as large as the coal industry there are efficiency engineers, men who earn their daily biscuits by scheming up ways and means to reduce the cost of production or of manufacture. Any piece of equipment or any method for lessening the cost of the product by even the smallest amount is eagerly investigated and, if it stands the light of this investigation, adopted.

Suppose that all delays, lost tonnage, etc., caused by poor rolling stock, locomotives and mine cars were charged up to haulage on the daily cost sheet. Suppose that the lubricant wasted around the mines and which should be in the wheels of this rolling stock were carried as a wastage item. Suppose that lost tonnage and lost day labor were charged up to mining machinery when the old, antiquated, much repaired, patched-up mining machines laid down and died, or, as they sometimes do, "played 'possum," how would all this appear on the daily cost sheet? Suppose that the time lost fooling with an old worn-out dump, repairing it and trying to get it to do the duty of a good one, were charged up to that particular piece of machinery on the tipple where it was installed. It would be reasonable, doubtless, to expect that some changes would be made.

If the losses caused by poor equipment could be charged (and they should be) to the direct cause of loss, and to that particular classification of costs to which they belong, many of the old worn-out and inefficient pieces of apparatus would be promptly replaced by modern, money-saving, time-saving and efficient equipment. There would be a man whose duty it would be to investigate and ascertain by what means every item appearing in the daily cost sheets could be made



more efficient—be made to do the same work for less money or more work for the same money.

Every mining man knows that the foregoing statements are substantially true, but they do not realize just what the numerous small items of loss amount to in a year's time; consequently, little effort is made to improve conditions. Put these items on the daily cost sheet in dollars and cents, and their importance is made immediately apparent.

The largest concerns in the coal business are among those who ignore these facts. I have in mind, however, one large concern that employs an efficiency expert. And if you doubt the utility of this expert, glance at the report of this company's excess profits tax. It will be an eye-opener, especially if it is compared with that of some of the other companies who produce about the same amount of coal in the same district from the same seams and sell in the same markets.

If anyone doubts the contentions I have here set up, let him look around in his own neighborhood, single out the man who has the best, most efficient, modern equipment, and compare his costs with those of the man who is worrying along with the same type of equipment that his father and grandfather used before

him merely because he *possesses* this equipment and *can* worry along with it. The time is coming when the coal operator will be forced to get a much greater degree of efficiency out of his equipment or go out of business.

Unfortunately, mining apparatus has a marked and pronounced proclivity for breaking down one piece at a time—for dying piecemeal. This imposes upon the operator the difficult problem of determining when the machine has been so thoroughly "shot to pieces" as to make scrapping advisable. A boon would be conferred on humanity in general and upon the coal operator in particular, by the manufacturer who could so design and build his equipment that it would fail as did the wonderful one-horse chaise—"to wonct."

Down on His Luck

A superintendent in charge of a Pennsylvania low vein mine was on his way to the office one morning when he met a miner going home. As he was short of men he asked the miner what the trouble was, and was informed by him that he was quitting.

"Why are you quitting?" asked the superintendent.

"Well, I don't have any luck here any more, that's why."

"What's the matter with your luck?"

"Well, I walked a mile to my room this morning, and after getting there I laid down and rolled 200 ft. into my place and landed with my back to the face. Rolled out and in again five times, and landed the same way every time. I'm going to the thick vein district."

Signaling in British Coal Mines Under the New Act

(Concluded from page 980)

primary cells, or from the colliery electrical service, the potential being reduced to 25 volts by the aid of a motor generator.

When a signal is sent from the bottom it rings the bell in the engine room and closes a switch, which connects the proper lamp with the battery or dynamo. At the pit bottom two possible arrangements are made, either what the makers call a switch selector and push, or a number of separate pushes. The selector is a multiple switch, formed by an arm sweeping over a number of contacts arranged on the arc of a circle. A pointer is provided on the outside of the selector, and the bottom cager moves the pointer to the number corresponding to the signal he wishes to give, and presses the push as many times as he wishes to sound strokes on the bell. The top cager has a somewhat similar outfit. With the separate pushes mounted on a board, and numbered according to the signals to be given, either the bottom or top cagers merely press the button corresponding to the number of the signal as many times as they require to sound gongs.

This apparatus requires rather a large number of wires in the shaft—as many wires as there are signals to be given, and one more. These may be separately insulated and made up into a multiple cable, and led to each signaling station. Where two or more beds are worked from the same shaft, the cager at each bottom will have a similar outfit, and provision is made on the indicator for each signal from each landing. The number of wires required will thus be increased by the number of additional signals. In my opinion, the use of multiple cables in the shaft is a disadvantage.

The signals are canceled automatically when the engine commences to move. In the case of the apparatus first described, this is accomplished by an additional electromagnet, whose circuit is closed when the engine commences to move. This is made to release the pawl holding the ratchet in position, a spring on the axle of the ratchet causing it to move back so as to bring the pointer and the flag to zero. In the indicator apparatus each signal wipes out the one that preceded it through a system of electric contacts. The last, or standing signal is of course only obliterated when the engine moves.

Another requirement of the new rules is that there shall be no sparking into a free atmosphere in any part of any signaling system. The system of signals that has been most largely employed on engine planes is one wherein contact is made between two naked galvanized iron wires, stretched on insulators along the side of the road. The naked iron wires must now be displaced by insulated wires and contacts made inside of gas-proof and flame-proof cases.

In one system, worked out by an eminent mining engineer, a number of switch boxes are placed at different points along the road and moving contact arms actuated in each, by mechanical-pull signal wires, arranged by the side of the road. Thus a signal can be sent from any part of the road, as with the old arrangement.

Winning the War with Coal

By Val Fisher
New York City

When the complete story of England's magnificent effort and sacrifice in the war is told, a chapter reflecting at once achievements among the most brilliant and revealing the debt of gratitude under which she has placed America through services to the American army must be given the prosaic title, "Coal." In the same narrative must be told how every man, woman and child in England went gladly without accustomed warmth last winter, through lack of fuel, in order that coal could be supplied in quantities sufficient to bring the American armies to France to stay the onward rush of the Germans last March, and in order that warmth and comfort could be supplied to them in proportion as every additional American soldier was landed in the battle zone. For the demand on England's already heavily-taxed coal supply was not only marked by every transport bringing troops to Europe, but for the maintenance there as stated, of every one of our boys.

English mothers and children bore this sacrifice gladly, as they have borne numerous others during the conflict. They even smiled at the announcements of the coal controller that their rations of fuel this winter, owing to the heavy demands of Italy, France and the United States in the manner explained, would be less than half those of previous winters. They even declared that they would save a quarter of their meager allowance, and all indications now point to the realization of the general ambition in this respect.

How 1917 Coal Output Was Consumed

An examination of the coal statistics of Britain in war time provides an interesting story. In 1917 the output was consumed as follows:

	Tons
Coal hoisted in 1917	248,000,000
Used at mines	18,000,000
Balance	230,000,000
Total exports to Allies, Neutrals and British possessions	35,000,000
Leaving a balance to be consumed as bunker coal, Admiralty requirements for munitions purposes, for domestic consumption and otherwise of	195,000,000

The causes of the shortage of coal for domestic consumption in England are several. The chief one, however, resulted from the enemy offensive last spring, when the Germans, owing to the Russian breakdown, brought their whole strength to bear in the West and seriously threatened the Allied line. The military situation affected coal conditions in two ways: (1) It was necessary for the safety of the Allied lines for England to comb out the miners for the army of resistance. The experts decided on making soldiers out of 100,000 mine workers. (2) The second attack in April in the north of France involved a serious loss in the output from those mines just behind the British lines that had been recovered from the Germans, thus rendering it vitally necessary for Britain to increase the supply of coal to France by several millions of tons a year, with the possibility of a still further increase in case these mines should be entirely lost. Owing to this possibility of further demand, the authorities decided to take but 75,000 men from among the miners for the army. In addition Britain was faced with fresh demands at home for naval and military purposes, the greatest item of which was that of the ever-growing American army in transport to France and when there.

We have been taught that coal is king, and this has long been accepted as an axiom, especially in commerce; but the story of how the English have used coal as a lever with which to enlist the aid of half the neutral world in winning the war for the Allies, leaves no doubt as to the truth of the saying. And too much could not be said for the business ingenuity and adroitness which has employed every ton of British coal to the advantage of the Allies. The whole story may not as yet be told, but enough of it may be indicated to demonstrate the brilliant talent used in our behalf.

It is a fact not generally recognized that as a result of Britain's coal supply and of her clever use of it neutral shipping is largely responsible for the presence to-day in France of the vast American army which took its part in the struggle. The shipping obtained with this coal also has been used in keeping France and Italy supplied with food, coal and munitions, to say nothing of the Serbian army and that at Saloniki and in Palestine.

British Coal Supply Used as Weapon

Thus it will be seen that the supply by Britain of coal to neutrals is not a matter of pounds, shillings and pence, but actually of life and death itself. Unless Britain sends coals to neutrals, Germany does so, her coal carrying with it the obligation of the recipient to send back in exchange food and products that may be used in furthering the enemy's supply of munitions of war. Though the Germans are in worse straits than Britain for coal, even so they are using it as a weapon in the manner indicated for neutral support to their utmost.

In short, the ability of England to send coal to neutrals is of both positive and negative value—positive in enabling her to barter for food, iron ore, etc., and shipping in return, and negative in enabling her to place a check on the export of war materials from neutral countries to Germany.

For instance, by supplying a definite quantity of coal to one country (Norway) England obtains the use practically of the whole of that country's mercantile marine, amounting to several hundred thousands of tons, in addition to foodstuffs and other necessities. Every cargo of British coal landed in that country means the use of one of its ships with which to carry coal to France or Italy or foodstuffs to these countries.

Britain uses coal in fighting Germany for the butter and foodstuffs of another country (Denmark). From this latter country she has likewise obtained the use of tonnage to a lesser though not an unimportant degree. And an arrangement with still another country (Sweden) has worked to material advantage in ships and important national products placed at her disposal.

Certain supplies of war materials from neutral countries to fortify Germany's effort have been either entirely stopped or reduced materially in return for British coal.

It is the trading power of British coal again that brings to her shores regular consignments of iron ore from still another country (Spain), this being sent back

to France and other theaters of war, of course in the form of munitions of all kinds.

Sir Guy Calthorp, the British Coal Controller, has taken care that the vital importance of coal as thus explained in the winning of the war should be made known throughout the length and breadth of the land, and the people understood the situation thoroughly. In order to prosecute a nation-wide publicity campaign, he induced Lord Northcliffe to lend, as chief of the publicity, the news edition of the *Daily Mail* and a regular editorial staff was organized by Walter Fish, the members of this staff writing daily on coal economy and its necessity in all its phases both for the metropolitan and country newspapers and periodicals, in addition to preparing pamphlets and handbills for distribution in this campaign of education. The crusade is being aided by officials high and low—the mayors of cities, members of Parliament, the clergy and school teachers everywhere—who have enlisted the aid of children in distributing pamphlets. It has been explained to the people that though England starts the present winter short of 30,000,000 tons of coal, some 9,000,000 tons should be saved by the rationing system. It is pointed out that though the deficit of 97,000,000 tons may not be found, it can be reduced only if the miners dig more coal and the householders use less than their ration. Even then the supplies of coal to the industrial world will be short of requirements.

Coal Supply Vital to Industry

The coal controller already has received deputations from a number of industries, such as woolen and pottery manufacturers, fabric dyers, bleachers, printers and finishers, pointing out that the reduction in coal curtailed the wage-earning capacity of their employees and threatens to inflict hardships on their work people.

Small wonder, then, that the people of England were impressed by the situation and as usual were willing and even glad to face the discomfort and rigors of a cold and damp winter in their usual ardor to aid in the speedy winning of the war!

The British coal controller recently distributed broadcast a hand bill containing the following:

COAL IS THE KEY TO VICTORY—MARSHAL FOCH

British coal supports the war in France. It is the great source of power. It is wanted for moving trains. It is wanted for driving ships. It is wanted for making munitions. It is wanted for high explosives. It is wanted to exchange for food and ships.

All the Allies want British coal and must have it. The Germans have seized French coal fields. Italy has none, America's coal is too far away. It is Britain's part to supply them all.

All the coal you save is used for war purposes—to bring victory nearer.

Another handbill gave details of how to save coal, telling users to mix coke with it, to take the coal out of the fire on going to bed to save the cinders, etc. Thus is coal being used in the interests of democracy.

Bituminous Coal Loaded at Lake Erie Docks During Month of October

Loading of bituminous coal for the lake trade at Lake Erie ports set a new high record in October, the revised and final report of the Ore and Coal Exchange, of Cleveland, shows. In the month 4,855,068.90 tons of cargo coal and 188,818.10 tons of vessel fuel, a total of 5,043,887 tons, were dumped. For the season to Nov. 1, the grand total of cargo and vessel coal now is 26,728,722,94 tons. This is a tonnage far in excess of that moved by lake in the corresponding period of any previous season. Loading of bituminous coal, including vessel fuel, for the season to Nov. 1 has been: April, 686,852.64 tons; May, 3,194,198.10; June, 3,539,352.30; July, 4,234,305.05; August, 4,996,929.95; September, 4,851,197.90; October, 5,043,887. The 26,728,722.94 tons of bituminous dumped in the season to Nov. 1 is divided into 25,611,125.94 tons of cargo coal and 1,117,597 tons of vessel fuel. The table shown above, the official compilation of the Ore and Coal Exchange, which is handling the Great Lakes vessel pool, gives the statistics in detail.

BITUMINOUS COAL LOADED AT LAKE ERIE PORTS

Port	Dock	In October			Season to Nov. 1		
		Cargo	Vessel Fuel	Total	Cargo	Vessel Fuel	Total
Toledo	Baltimore & Ohio	569,964.65	15,205.65	585,170.30	2,707,235.85	58,729.45	2,765,965.30

In a statement to the public the coal controller says: "Notwithstanding economies already made, we are still on the danger line and the facts cannot be too insistently and too often brought to the notice of the people of this country. The stocks of our munition works are being eaten into, gas and electric companies are crying for coal to build up their stocks against the winter months. These stocks are not being accumulated at the present time; they are being drawn upon and we have not been able to fulfill our coal obligation to our Allies. The miners' leaders have promised to do their utmost to induce the men to increase the output, and the public is being asked to do its part in reducing the consumption of coke, gas and electricity to a minimum. It is a race with winter. Every consumer should try to manage on three-quarters of his ration. The quarter saved will help to keep our brave soldiers warm."

One pound of pure carbon produces, when completely burned, about 14,500 B.t.u. and requires about 12 lb. of air for its combustion. However, commercial fuels contain combustible matter which forms the ash; this inert combustible matter uses up heat when it is raised to the temperature of the burning fuel.

Use of Methane as a Fuel

By George W. Williams
Wilkes-Barre, Penn.

The milions of cubic feet of methane which are drawn by fans daily from the anthracite mines, in order to make mining less hazardous, may possibly be harnessed, despite the contrary view of many experts, and utilized in a commercial way. The combustibility of methane is not disputed, but whether this terror of the mines, pure or in a mechanical mixture with air, can be put to use as fuel is a matter that men of thought and vision are trying to work out in the hard-coal fields.

Two big problems relative to the possibility of giving methane a commercial value are now in the hands of mine students in the Wyoming Valley. The first of these, and probably the more important, is to determine the value of the methane content of mine air. The second is whether the return air from mines, containing 1 per cent. of methane and less oxygen than pure air, can produce a greater heat for the coal consumed than can pure air alone.

Most problems of this sort are eventually solved through study and experiment, and it follows that any coal corporation sufficiently interested to go to the expense and trouble of almost public experiment must have found some fact in laboratory work on which to base expectation and hope.

Months ago Governor Martin Brumbaugh of Pennsylvania wrote to an official of the Delaware, Lackawanna & Western, Coal Department, and suggested that the millions of cubic feet of methane going to waste and the millions of cubic feet more left untapped in the earth be put to some practical use. That message did not fall on deaf ears, for out of it has grown, following long study and work in the laboratories of that company, a determination to test in some conclusive manner the possibility of commercially utilizing methane—a question that has enthusiastic champions and perhaps just as positive antagonists.

At the Loomis colliery of the Delaware, Lackawanna & Western Co., at Nanticoke, Penn., there has been erected an experimental station that may quickly and without danger of contradiction decide the question of the commercial worth of methane. It is not the type of plant that denotes permanence, neither has it an expensive foundation. It does not give evidence of coal company lavishness. It does represent a purpose, however, and what it lacks in substantiality and cost is fully made up in the determination back of the motive—the earnest zeal for solving one of the unique mine questions of the century.

This experimental station was erected at the direction of W. W. Ingliss, vice president and general manager of the Delaware, Lackawanna & Western Company, and stands in close proximity to the big Loomis breaker. It takes form in a locomotive boiler fitted with a smoke stack about 30 ft. high. Fifty feet distant is the big mine fan of the Loomis colliery, which for years has been throwing the impurities of the mine into the atmosphere. To conduct these to the boiler an airway has been built.

EXPERIMENTAL STATION ERECTED AT NANTICOKE, PENN., TO TEST AVAILABILITY OF METHANE AS A FUEL

The natural operation of the fan would be to throw out its mixtures above the mouth of the feed line. To divert the course of such mixtures a smaller fan has been installed in the airway 6 ft. from the intake, and by this means a certain amount of air is shunted and forced to the base of the boiler. Thus instead of taking air from the atmosphere for the purpose of burning coal, the current comes from the fan drift; and here comes the chance to experiment with the first of the big questions to be determined—that of learning the value of the methane content of mine air, the plan being of course to consume or take advantage of the methane constituent of this air, which is about 1 per cent.

It is stated that the first experiment will be made with this equipment while connected with the mine drift, and that after the value of the methane content of the air has been determined further tests will be made by obtaining the air supply from the atmosphere.

The principle of the experiment is plain. In determining the value of methane in the return air current a unit weight of coal will be consumed and the water evaporation noted. The equipment will then be changed in order that the air supply be obtained from the atmosphere, under which condition an equal unit of coal will be burned and the water evaporation noted for comparison.

At this point the second of the big questions presents itself. It is well known that the return air from the Loomis mine contains 1 per cent. of methane. As a matter of fact it contains less oxygen than is found in the atmosphere. Oxygen is the supporter of combustion, and in the return air from the mine oxygen is present in less degree than in atmospheric air. Whether the return air can produce more heat for less coal consumed than pure atmospheric air becomes then a most interesting matter.

Comparisons are always of interest. In the case of the Loomis experiments the existing facts may afford interesting study. Analysis of pure air, as all mine students know, shows the following: O, 20.93 per cent.; CO_2, 0.03 per cent.; N, 79.04 per cent. State reports show the analysis of Loomis mine air to be O, 20 per cent.; CH_4, 1 per cent.; CO_2, 0.07 per cent.; N, 78.93 per cent.

Will the return air, with 1 per cent. methane as shown in the foregoing analysis, and its 20 per cent. of oxygen, produce results equal to those secured when using pure air containing 20.93 per cent. of oxygen?

The Loomis is one of the most gaseous mines of the Wyoming Valley. Two fans are constantly in operation drawing impurities from the underground workings. The larger of these draws off every 24 hours 3,451,680 cu.ft., or 77.6 tons, of methane. The smaller one throws off 2,462,400 cu.ft. each 24 hours, or 55.4 tons, making a total of 5,914,080 cu.ft., or 133 tons of combustible gas exhausted from this mine each day.

Just what will be the result of the Loomis experiments is problematical, but they bring forcibly to light the fact that a big company and capable men are just now groping in the darkness, as it were, on the methane question. While they have not as yet laid their hands on facts and conditions that indicate any revolution in the anthracite industry, they are thinking and working, and out of their earnest effort is certain ultimately to come definite conclusions as to the possibilities, positive and negative, of the great methane question.

Treatment of Burns with Wax

The war has revolutionized surgery, and perhaps in no way more completely than in the treatment of burns by the wax method. The men of the mines, whether official or subordinate, have had for many years such an expert knowledge of the dressing of burns, obtained by them in first-aid instruction, that everyone in the industry will be interested in a new method of treatment in which a preparation of paraffin wax applied hot replaces all the old medicaments, some of which tended to spoil and become septic and none of which gave perfect satisfaction even when correctly applied. The wax, or Ambrine, becomes liquid at about 120 deg. Fahr. After being heated to a sterilizing temperature for 10 minutes it is placed in a water-jacketed atomizer which keeps it at a temperature of between 140 and 150 deg. Fahr. Before application the burns, regardless of character, are thoroughly dried. Then an air-tight covering of paraffin wax is applied to the burned area and allowed to extend a half inch beyond it. A thin layer of cotton is then laid over the waxed area and is incorporated into the first film of paraffin wax by painting with a fine varnish brush sufficient wax to completely impregnate the cotton. The wax "sets" in a few seconds. The dressing is then completed by swathing the entire waxed area in cotton and bandages. Every 24 hours the burns are redressed. The wax tends to splint the wound and to keep the temperature constant and favorable for skin renewal and repair. In a short time secretions form under the dressing, and these make the wax nonadhesive so that it can be readily removed without pain or injury. As soon as the granulating area shows only slight secretions, the dressing may be renewed every 48 hours.

The new wax treatment was invented 16 years ago in China by a Frenchman, Barthe de Sandfordt, but it did not make much headway. Five years ago attempts were made to market it in America but without much success. The war developed the treatment so rapidly that now it has received almost international indorsement. The United States army purchased during the war no less than 5000 to 6000 lb. of the Ambrine wax per day, the whole product of the factory. Even then enough was not being produced to satisfy the demands.

Ambrine can be used successfully not only with superficial burns but with those of second and third degrees of severity. It is used for the treatment also of cuts, lacerations, abrasions, amputations, chilblains, frost bites, bruises, sprains, boils, whitlows and most forms of skin affections. It really does not cure the injuries described but gives nature the chance it desires to do its own curative work. Many of the methods used today and in the past involve such painful operations in dressing the wound that the operation is not only terribly distressing but retards the cure of the afflicted member and leaves the patient permanently disfigured.

According to William O'Neill Sherman, chief surgeon of the Carnegie Steel Co., in his paper, published in April of the present year in *Surgery, Gynecology and Obstetrics*, an article, by the way, submitted by request of the Committee of Medical Research of the Council of National Defense: "To seal up an infected wound was thought to be contrary to all sound surgical principles. Nothwithstanding this, the patients [at Issy-les-Moulineaux] were being dressed without pain; they were recovering in one-third to one-half the time required under former methods and free from cicatricial contraction with a minimum of scar tissue."

He adds: "Very few who have witnessed this treatment at first hand have failed to acknowledge its unquestioned superiority over every other known method."

According to Dr. Sherman improvements of technique in the United States have made it possible to dress "the largest burns in 5 to 8 min., without much discomfort or annoyance to the patient." The men in the employ of the Carnegie Steel Co. having learned from the experience of their fellow workmen are beginning to ask that the method be used in their treatment.

Occlusion of Explosive Gases in Coal

By JAMES ASHWORTH
Consulting Mining Engineer, Vancouver, B. C., Canada

SYNOPSIS — *Authoritative tests of coal dust show presence of ethane. The gas also found in samples of mine atmospheres. Possibilities of occluded gas existing in a liquid form, under high pressure, suggested by the continuous outflow of gas and dust, in the outbursts at the Morrissey mines. Methane given off largely by coal; but ethane and propane yielded mostly by fine dust, which emphasizes the dangerous nature of such dust. Safety to be sought in a careful study of best methods of working coal mines.*

AT FIRST, it may seem a ridiculous question to ask, "In what way is gas held in coal seams?" The majority of mining people will immediately reply that it is held in the crevices, cracks and bedding planes common to the coal formations. It has, however, been well known to many close investigators that the solution of the question is not simple.

Some years ago when I first visited British Columbia, and the Crow's Nest Pass coalfield in particular, I formed the opinion that ethane (C_2H_6) was a component part of the so-called firedamp of the mines. This opinion was confirmed, a little later, by tests made on fine coal dust, collected and taken to England in sealed canisters. The tests were made by Prof. Phillips-Bedson of the Armstrong College, Newcastle-on-Tyne, whose fame as an investigator of the gases occluded in coal is world wide. A few years later, these results were confirmed by Prof. John Cadman (now, Sir John), who discovered ethane in a sample of the atmospheres of the Belle Vue mine, which is on the Alberta side of the Crow's Nest Pass.

Discovered Ethane and Hydrogen in Analyzing Samples of Mine Air

Later still Dr. Haanel, chief of the Dominion government laboratories at Ottawa, discovered ethane and also indications of hydrogen in samples of mine air submitted to him for analysis. Again, the British Columbian Minister of Mines' report for 1917 contains some extended information on this subject, as the result of an investigation made by George S. Rice, Chief Engineer of the United States Bureau of Mines, while investigating the cause of "bumps" at Fernie.

The analyses and tests of gases and coal dusts, made by A. C. Fieldner, chemist of the United States Bureau of Mines, who developed some new methods of testing coals for their occluded gases, showed the average percentage composition of the coals tested was as follows: Moisture 0.51; volatile combustible matter 26.62; fixed carbon 66.78; ash 6.10; sulphur 0.37 per cent. All the samples, after gathering, were placed in sealed jars, so as to retain any gases that might be given off in transit. However, on opening some of the jars under water it was found that they were at atmospheric pressure, and any gas that may have been given off had escaped. These samples were all obtained from the coal seams in nut-sized pieces.

In mines of a gaseous character, explosive gases are usually found to be highly compressed; but, in the tests so far made, in the Crow's Nest Pass Coal Company's Coal Creek mines, no high pressure gas was found, although hydrocarbon gases were found to be held in the structure of the coal and classed as "occluded" gases. Careful microscopic examinations of coals have disclosed the fact that some coals contain large quantities of microspores and megaspores, which are known to be the seeds of mosses.

This particular subject has been, and is still, the life-long work of James Lomax and his daughter, at Bolton, England. They and their friends hope to be able to determine, by this means, what coal seams are particularly dangerous both in respect to gas and dust. I feel, however, that this does not offer the best solution to the problem of mine explosions.

Do Occluded Gases Exist as Liquids in Coal?

For some years past, probably since 1904, I have been of the opinion that some of the most dangerous explosive gases exist, in many coal seams, in the form of liquids, which when the pressure is reduced break away the coal, and continue breaking it away until exhausted. In no other way can I account for the extremely dangerous and destructive effects of the outbursts of gas that have occurred, from time to time, in this district, especially in the Morrissey mines of the Crow's Nest Pass coalfield.

In practically all the cases that occurred, the outbursts of gas continued for some considerable time, and were of such volume that the gas came out of the mine at the intake opening, while the fan on the return opening was running at full speed. With the rush of gas came, also, great volumes of coal dust as fine as soot. The total weight of dust, in one case, was estimated at five thousand tons. The cavities left by the displacement of the coal were, in all cases, at right angles to the strike of the seam. It is easy to understand that if this gas had been compressed in a cavity already existing, it would have burst forth in one huge volume, but that was not the case.

Reading a recent publication of the U. S. Bureau of Mines, Bulletin 148, by J. O. Lewis, entitled "Some Physical Properties of Petroleum and Gases," my attention was arrested by the following statement regarding the solubility of gases in petroleum:

> Under the same conditions of temperature and pressure, a particular oil will absorb a fixed proportion of a particular gas; but this proportion or "coefficient of absorption," as it is called, varies with each oil and each gas. The gas is held absorbed in the oil in the same way that soda water is charged with carbon dioxide. The proportion of gas absorbed is lessened under high temperatures, but is greatly increased under high pressures, in accordance with Henry's law of gases. Enormous quantities of gas are held in solution under the high initial pressure found in some oil wells. Some of the constituent gases are condensed at these high pressures just as in a compressor plant; and, as long as a

high enough pressure is maintained, exist as liquids dissolved in the oil. Under such conditions the gas is not absorbed as a gas, but as one liquid dissolved in another; and a much greater proportion of gas can be held in solution when in liquified form than when uncondensed. Other gases (methane, ethane and propane) are never liquified at the pressures and temperatures in oil sands penetrated by wells, but are always found as gases dissolved or absorbed in the oil. They constitute the so-called dry gases.

In testing the Coal Creek (Fernie, B. C.) coals for their occluded gases Mr. Fieldner did not air-dry them but ground them up in a special mill. The results that he obtained were 37.6 c.c. of methane, and 126.0 c.c. of ethane, besides 11.9 c.c. of carbon dioxide and 24.4 c.c. of nitrogen, making a total of 199.9 c.c. of gas from each 100 grams of coal. It is very noticeable that, in transit from the mine to the laboratory, practically no methane, ethane, or carbon dioxide were given off. That the ethane was not produced from the heat generated during the grinding was proved by the fact that in some of the tests made of coal from the same mines no ethane was found.

Samples of coal from the Nanaimo mines showed that coal from No. 1 mine contained 62.7 c.c. of methane and 21.9 c.c. of ethane, per 100 grams of coal, while another sample contained 128.6 c.c. of methane, and 29.8 of ethane. But samples taken from the Reserve mine, where a disastrous explosion occurred a few years ago, showed that both ethane, propane and methane were present. One sample from this mine yielded 20.5 c.c. ethane and 5.7 c.c. propane; another sample, 5.0 c.c. ethane and 11.9 c.c. propane. Tests made on special samples of mine air sent to the Canadian Department of Mines, from Michel, showed a trace of hydrogen in two cases, but no ethane.

Methane Given Off by Coal, While Ethane and Propane Yielded by Fine Dust

From the above tests it would appear that methane is readily given off by coal, while ethane and propane are found more frequently when the coal is finely crushed. Some physicists assert that films of gas are held, on the surface of the particles of coal, under such tension that the gas is in a compressed state equivalent to liquefaction. It has been found that large volumes of gas are continuously given off from the working face, particularly in some of the Michel mines, as reported by the chief inspector of mines, in the British Columbia Minister of Mine's report for 1916.

In the tables appended to the report just mentioned it appears that the volume of gas found in the return air and classed as methane, is very large, and it has been found necessary to limit coal getting at the faces to one shift, each 24 hours. The tabulated percentage of explosive gases carried by the return air does not include all of the occluded gases in the coal. Mr. Fieldner's investigations reveal the presence of other hydrocarbon gases, such as ethane and propane, and a suspicion of hydrogen, in each minute particle of coal dust. It follows, therefore, that the fine coal dust is of an especially dangerous character.

Having ascertained with almost absolute certainty the way in which explosive gases are contained in the structure of coal seams, it now becomes necessary to ascertain in what way the mines can be worked with the greatest degree of safety. The evidence shows that the mines of the Crow's Nest Pass are generally worked on some form of pillar-and-stall system. It has also been shown that every pillar is a constant producer of highly explosive gas, and it follows that the greater the number of pillars, or more properly speaking, the greater the superficial area of coal exposed the greater will be the difficulty of ventilating the mine safely.

In regard to this mode of working a most extraordinary statement is made in Mr. Rice's report (British Columbia, Report of the Minister of Mines, 1917, p. 327) to the effect that during the big "bump," Nov. 8, 1916, no gas was given off. No suggestion or explanation of this is made, although, at a later date, a smaller bump in the same mine produced a large volume of gas. All but one of the bumps recorded at the Coal Creek mines have been accompanied by outbursts of explosive gases. I feel convinced that further investigation will fully bear out this short summary of the way in which explosive gases are held in a coal seam; and it only remains to discover the safest method of working coal seams to vastly improve them in point of safety.

Effect of Salt on Reinforced Concrete

It has frequently been recommended that salt be placed in the water used to mix concrete in freezing weather, in order to decrease the liability of the concrete freezing while setting and hardening. A writer in *Concrete*, who was an observer for a period of 12 years of the effect of salt on reinforced concrete in a warm climate, concludes that salt should never be used in the construction noted. While the observations recorded were made on reinforced concrete in the Hawaiian Islands, where there is a warm, humid climate, still the failures of the structures were so serious and occurred within such a comparatively few years after construction that the use of salt in connection with reinforced concrete is questionable practice in any section.

A case was cited where four years from the time of completion, cracks were observed in a reinforced-concrete structure, with rust discoloration. There was evidence of internal stress which produced a bulging of the surface—the action on the concrete created by the corroding steel. It appeared that there was no protection to the steel by concrete where salt water was used in the mixing. While in the writer's opinion the action on the reinforcing was many times greater in a warm climate than in a cold one, nevertheless all engineers might well consider the possible danger to reinforced structures from the use of salt in the mixing water. In observing structures which showed failure on the Islands, everyone of them was exposed to salt influence, in many cases a small amount, but nevertheless disintegration had been abnormally fast. The structures in question had either been built under his own observation or he had carefully investigated the specifications and methods of construction.

Coal Mining Institute of America

Instead of being held at the Fort Pitt Hotel, Pittsburgh, Penn., the meeting of the Institute scheduled for Dec. 4 and 5 will convene in the auditorium of the Chamber of Commerce. The Institute Dinner will be held in the English Room of the Fort Pitt Hotel.

Difference of Opinion Exists Regarding Retention of Zoning Plan

The proposed retention of the zone system by the Fuel Administration is bringing out varied opinions from railroads. Some are insistent that the zone system should be abolished, while others maintain that it is an innovation which should have been put in force many years ago. An analysis of the opinions expressed, however, show that the question of getting coal cheapest is the ruling factor. In certain cases where the retention of the zone system will mean cheaper coal in some districts, the railroads are anxious to have the zones retained. In other regions, where exactly the opposite condition prevails, the railroads are urging the abandonment of the zones.

Changes To Be Made in Anthracite Budget

Areas farthest from the mines, or those which have obtained only a small proportion of their allotment, are to receive anthracite supplies first. A readjustment of the anthracite budget has been made necessary by decreased production. Owing to well-distributed reserves of bituminous coal, it is believed that no particular hardship will result even if it should prove impossible to supply the full quota of anthracite. Shipments of anthracite to the Northwest by way of the Lakes will end with the sailings of Nov. 30. New England is to receive 100 carloads daily. It is estimated that the production of anthracite has been reduced by 1,680,000 tons because of influenza and the celebrations of the signing of the armistice.

No Shortage of Coke Expected

While no slump is expected in the demand for coke, the prevailing opinion in Washington is that production needs no further stimulation. If it were not for the reduction of output caused by influenza, there would even now be more coke than is being called for. Probabilities indicate that many of the ovens built to take care of the war demand must be abandoned sooner or later. The increased number of byproduct ovens also has an important bearing on the situation. It is estimated that 1,000,000 tons of byproduct coke which have been going into war industries now will be available for other purposes.

During the war, it is estimated that the maximum tonnage of coke which was moved by the Fuel Administration, contrary to the intention of the producers, in no month exceeded 2 per cent. of production; that is to say, the maximum amount interfered with did not exceed 50,000 tons in any one month.

The cordial coöperation of the coke operators is coming in for warm praise. One of the greatest factors in saving the several serious situations which arose in coke supply is said to have been the unusual faithfulness and pluck of the workmen in the Connellsville district. The same cannot be said of labor in the Alabama district, however, where the high percentages of absences from work greatly interfered with production.

Would Abandon Government Coal Prices

Suggestions that the price schedule be abandoned are reaching the Fuel Administration. The desire for that action, it is said, comes largely from the producers of high-grade coals, the price of which probably would rise if the present maximum were removed. The principal argument for the removal of the price schedule is that the established maximum tends to stabilize a higher price to the public than is justified in the district where there is a surplus of coal.

Railroad Congestion Hampers Coal Movement

An unexpected difficulty has arisen which is hampering coal distribution. The signing of the armistice has brought up the question of what disposition to make of Government property intended for war use. Many thousands of freight cars were loaded with munitions and other war materials. They are no longer needed in France. As a result they have been placed on sidings, wherever possible, and are jamming many ports. Facilities for unloading and storing such great quantities of material are not available at many places where these cars are held awaiting orders. As a result a large amount of rolling stock is tied up while yards and terminals at many points are badly congested.

Far West Has Plenty of Coal

A surplus of coal exists throughout the entire country west of the Mississippi River, according to S. L. Yerkes, assistant director of distribution for the Fuel Administration. Mr. Yerkes just has returned to Washington after a tour of the western coal fields. Oil has been fairly plentiful in the far West throughout the war. Mr. Yerkes' investigation showed that there had been little substitution of coal for oil.

Considerable movement of coal is now in progress between Utah and the Hawaiian Islands, but Mr. Yerkes

is not at all sure that the exportation of Utah coal to the west coast of South America can continue after the shipping situation eases up. The advantages of having a higher grade coal, a shorter haul to the seaboard and a shorter steaming mileage favor the recovery of this business by the mines near the east coast.

Coal-handling facilities at Pacific ports are ample for present and prospective needs, Mr. Yerkes reports. The facilities at San Francisco will be improved materially in the near future by the installation of a new plant of large capacity to handle both cargo and bunker coal.

Mr. Yerkes returned by way of New Orleans, where he advised with the Board of Commissioners of the port with regard to plans being made for improved coal-handling facilities there. He approved of plans for facilities handling 300 tons per hour. In this he differs from views held at the Shipping Board that a much larger plant should be put into operation at New Orleans.

Anthracite Miners To Be Released from Service

Thousands of anthracite miners are to be released from the army to aid in increasing the production of anthracite coal, the United States Fuel Administration announced on Nov. 20. Telegrams bearing instructions to this end have been sent to all camps in the United States by order of the Secretary of War, who acted on the request of Dr. Garfield.

The instructions of the Secretary of War direct that anthracite miners be segregated and sent to Washington, where those who desire to resume their work in the anthracite fields will be given immediate discharge. The need of increased anthracite production was strongly urged to the Secretary of War. This production, it was pointed out, has been cut 25 per cent. in six weeks by influenza and through the falling off in production inevitable upon announcement of the armistice.

Middle West Traffic Situation Good

Commenting on the traffic situation in the Middle West, as it affects coal, Hale Holden, regional director of railroads, says:

Coal loading generally for the central western region showed an increase of 15.5 per cent. during October. In the western fields of Colorado, Utah and Wyoming there is every evidence that the market was kept completely full of coal. The coal situation in Illinois and Indiana has been most satisfactory and the loading has exceeded all previous months of the year except July, which was the record month. The reports of the fourteen roads that originate 90 per cent. of the bituminous coal produced in Illinois and Indiana totaled the following:

	October
Cars loaded, 1918	189,772
Cars loaded, 1917	157,139
Increase over previous year	32,633 — 20.7%

Adding 10 per cent. for production on non-reporting roads gives a total loading of 208,749 cars in October as compared with 220,701 in July, 202,658 in August and 189,843 in September.

Notwithstanding the heavier loading, there was less complaint of car shortage than in any similar period during the past seven months. The only serious car shortage in October was on the C. C. C. & St. L. R. R., but that has been corrected and mines on that road are now enjoying full car supply.

Production of coal in these states has overtaken consumption. This was recognized by the Fuel Administration and all restrictions against furnishing bituminous coal for non-essential or non-preferential uses, even including country clubs, have been withdrawn. During the month some mines were closed for a time for lack of market, and unbilled coal in cars awaiting sale is appearing at the mines in certain fields at times in considerable quantity. As a result, some of the mines have temporarily suspended operations because, under the rules for distribution of equipment, unbilled carloads of coal are counted as cars furnished and with these on hand the rules do not permit of placing enough additional empty cars to justify resumption of operations until the unbilled coal is disposed of. Under rules of the Fuel Administration this coal could not be shipped on consignment, so it was necessary for the producer to hold the coal in cars on track or reduce the price, which has resulted in what the coal trade calls a soft market.

The outlook for the winter is better than it has been since the fall of 1915. The country is stocked up to a greater extent than ever known before. The car supply in October was better than it has been during any sustained period since July, 1916, and the mines are producing more coal than ever before in their history.

All things considered the Railroad Administration can, in respect of fuel supply, view the future in this region with serenity, confident that there will be no lack of fuel through any failure of the transportation system.

Nims Resumes His Law Practice

Harry D. Nims, formerly assistant United States Fuel Administrator, with the proximity of peace has secured his release from the heavy artillery officers' training camp at Fort Monroe, and has returned to his law office, 32 Nassau St., New York.

Fuel Administration Will "Carry On"

Despite numerous requests for reconstruction statements, the only statement which has been made at the Fuel Administration is in essence as follows:

The United States Fuel Administration, which will be terminated automatically upon proclamation of peace, will pursue its course with that end in view, relinquishing its various activities as they become unnecessary under armistice conditions, and continuing to function where its services still are required.

Reports of immediate and wholesale dissolution were said to be without foundation. Various subdivisions already are in process of winding up their duties. The Mine Track committee, and some other sections including several from the Oil Division, have been released at their request from further service, because the work which they undertook to do has been done.

Whatever machinery is necessary to the continuation of the full discharge of the duties of the administration will be retained until these duties are discharged or until the administration is relieved of them, and continuation of the larger activities of the administration through the winter was said to be the present prospect. The vigorous and careful supervision of anthracite coal was cited as an instance of the kind of work which still must be done.

The proper administration of the zoning system, under which millions of car-miles of haulage were saved and the supply of coal was correspondingly increased, was mentioned as another of the sort of duties which the administration cannot abandon forthwith, and which it will carry forward.

New West Virginia District Representative

Effective Dec. 1, R. B. Isner, of Elkins, W. Va., has been appointed district representative to succeed D. R. Lawson, of Fairmont. Mr. Isner has had long experience in handling coal matters in the district to which he is assigned. He is sales manager of the West Virginia Coal and Coke Co. Mr. Lawson has the distinction of having been the first district representative of the Fuel Administration. He is resigning to enter the coal business.

Bituminous Storage Limit Off

All storage restrictions on bituminous coal were removed on Nov. 22 by the United States Fuel Administration in conformity to the action of the War Industries Board in cancelling its preferential industries list. Anthracite coal is not affected, however, by the ruling of the Fuel Administration.

Every industry and every householder in the country now may store as much bituminous coal as desired or obtainable, as the action of the War Industries Board removes the necessity for the Fuel Administration to distinguish longer among different classes of industrial plants.

The restrictions just raised provided for the accumulation by the consumers in the preference classes defined by the War Industries Board, of reserve stocks of bituminous coal, in accordance with their location in relation to various mine fields and their classification on the preference schedule.

All industries located farthest from distribution points, particularly those in New England and in the Northwest are found not only to be well stocked, in accordance with Fuel Administration specifications, but in many cases have surpluses above those amounts.

Senate Investigating Coal Industry

The relationship between the increase in wages in the anthracite field and the amount added to the price of anthracite coal is to be probed thoroughly by the Senate Committee on Manufactures, it was indicated at the initial hearings. While the anthracite situation is to be gone into first, it is understood that a general survey is to be made of the activities of the Fuel Administration. The Committee on Manufactures, of which Senator Reed, of Missouri, is chairman, conducted an investigation of the coal situation last winter. Tactics employed during that investigation oftentimes were such as to be characterized as abusive and demagogic. That similar procedure may be expected from this investigation is predicted by some.

Senator Reed is starting out to establish that the anthracite shortage could have been met last year by washing culm banks; that culm banks were not washed to capacity because coal operators feared they would flood the market; that the Fuel Administration did not use its authority to compel coal operators to work culm banks; that the Fuel Administration either is controlled or "worked" by the anthracite operators.

James B. Neale, the director of production for the Fuel Administration, and an anthracite operator, was examined at length, but the information which he gave in reply to inquiries tended to show that the preconceived notions of the committee's chairman were based on faulty premises. Arthur Learoyd, also of the Fuel Administration, replied to inquiries in regard to the distribution of anthracite which is being attacked by some of the Senators from areas denied this type of fuel. The anthracite situation in New York City was discussed Nov. 9.

Coal Loading Ahead of Last Year

At the close of business Nov. 9, 698,661 cars of coal had been loaded during 1918 in excess of those loaded during the corresponding period of 1917. Loading during the week ended Nov. 9 is reported by the Railroad Administration as follows:

	1918	1917
Total cars bituminous	178,535	195,006
Total cars anthracite	32,525	38,571
Total cars lignite	3,456	4,639
Grand total cars all coal	214,516	238,216

Zoning Eliminates Waste Haulage

Close to 200,000,000 car-miles will be saved during the present coal year by the zoning system, it is estimated at the Fuel Administration.

Early estimates were that the movement of bituminous coal affected by the zone system would involve about 300,000,000 tons, or 60 per cent. of the total production. The latest figures show that 368,858,000 net tons of this kind of coal have been produced and delivered since Apr. 1, 60 per cent. of which is affected by the zone system.

These later figures show that even more than the originally estimated 160,000,000 car-miles will be saved in round trips to and from the mines and that considerably more than the 300,000 additional trips, which the saving in car-miles would effect, will be made. Exact figures have not been compiled, but the early estimate allowed for the 300,000 additional trips being the equivalent of 5 per cent. increase in the production.

Brief Washington Notes

Restriction in the use of electricity for outdoor illumination has been left entirely to the state administrators. The national lightless night order has been cancelled, as of Nov. 20.

A policy of permanent Government ownership of coal mines and oil wells, along with railroads and the telegraph, is provided in a bill introduced in the Senate by James Hamilton Lewis, of Illinois.

A large solid silver loving cup was presented to James B. Neale by the members of his staff at the Fuel Administration on Nov. 20. The presentation was made at a dinner given for the occasion.

Coal zones L and M have been modified so as to relieve the Chesapeake & Ohio R.R. Producers in those zones now are permitted to ship into a portion of Indiana and into an increased portion of Ohio. The producing districts affected are in West Virginia and Kentucky.

Representatives of the anthracite industry have been sent to the military camps at which anthracite miners are in training. They expect to seek out the miners and try to induce them to return to that industry. They also will take the necessary steps to secure the preferential discharge of such men.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Now that the pressure of industry for more bituminous coal has entirely ceased, the Director of Production proposes to concentrate his attention on the output of anthracite, which has fallen considerably and seems hard to raise to its former level. James B. Neale has gone back to the anthracite region to do there a work larger, and one, in many ways, more difficult, than that which he tackled in western Pennsylvania and West Virginia.

The war had a peculiarly urgent appeal on the bituminous mine workers and one that, as it was new, had a more direct hold on the heart strings. The anthracite appeal is not of the same character, being civil rather than military. It comes, too, after a long period of coaxing and urging and at a time when those in other industries are letting up. It is hard to work more steadily than ever while your friends are celebrating. Much therefore is asked of the anthracite men, but, much as it is, it is quite to be expected that they will rise to the occasion. Those choice spirits among the hard coal mine workers whose work has made up for the slackness of others will still lead in devoted service and will repair the deficiencies of those who fail to visualize their duties and opportunities to serve.

TONNAGE LOST IN JUBILATION AND INFLUENZA

The daily anthracite tonnage has been largely reduced by celebrations. On Monday, Nov. 11, every colliery suspended in the Lehigh region except Hazlebrook and Coleraine, and these are both small operations. The influenza epidemic is still a big factor in reducing colliery output. The public has assumed that, once the epidemic ceases, work will go on as ever. But it must not be overlooked that many of the victims are dead and those who have recovered from the disease are too weak for active mining for at least two weeks. In some places the disease arrived late, as at the village of the Sandy Run Colliery. After other places were for the most part clearing themselves from this disease, Sandy Run was experiencing the full force of the epidemic.

The reopening of the saloons, closed by reason of the influenza, caused a wave of drunkenness to sweep over the anthracite region. Those who were inclined to imbibe to excess took advantage of the change and celebrated the end of the war alcoholically. Though the bulk of the English-speaking mine workers are temperately inclined there were enough others to cause a large reduction in output.

The ban on public meetings is removed and this has naturally resulted in some union activity. Local union No. 311 of Plymouth, Penn., has threatened to strike unless the increased wage scale in the anthracite region is dated back to Oct. 1 instead of to Nov. 1 as Dr. Garfield provided. A delegation from the union was appointed to go to Washington and endeavor to have this change made.

The increase in the wage rate of the mine workers in the anthracite region has caused discontent among the firemen and coal shovelers of the Scranton Electric Co. These men get $3.69 per day and want an increase of 33 per cent. or roughly $5 per day.

In West Virginia there is still some discontent. President C. F. Keeny of District No. 17 of the United Mine Workers believes that the wage rate of the West Virginia field should be brought to an equality with the wage rate in the Indiana field and in other fields of the competitive region. The drivers in the West Virginia field receive $4.52 a day, whereas the drivers in the other fields referred to receive $5.

On Nov. 19, John P. White, joint director of the Bureau of Labor in the Fuel Administration, presented his resignation to Dr. Garfield, but he will still be available for consultation. The resignation becomes effective Saturday, Nov. 30. In his letter to Mr. Garfield Mr. White pointed out that only a few labor disputes remain to be adjusted and added:

"I believe that I voice the sentiment of the officials of the miners' union when I state they desire to continue their affiliation with the Fuel Administration and to coöperate with it to the fullest extent until peace is promulgated."

In his acceptance, Dr. Garfield pronounced Mr. White's services "of inestimable value." The letter continued:

"It gives me pleasure to convey to you also the appreciation of the President, which he expressed to me on the several occasions when I informed him regarding your work as a member of the Fuel Administration."

Wages in Shamokin District

The new wage scale for day laborers in the ninth district as constituted by the United Mine Workers of America was announced by James Matthews, president of the district, on Nov. 19. It will be in force until the signing of the peace terms or until Mar. 31, 1920, in case peace is not signed by that date.

	Per Day
SHAFT WORK	
Chargemen	$6.10
Machine Runner	5.28
Machine Helper	4.73
Muckers	4.63
Blacksmiths	5.41
Topmen	4.10
TUNNEL WORK	
Chargemen	$6.04
Machine Runner	5.17
Machine Helper	4.63
Muckers	4.47
Mucker Boss	5.15
Blacksmith, on big machine	5.26
Blacksmith Helper	4.31
SMALL MACHINE AND SHAFT WORK	
Chargemen	$5.99
Small Machine Runner	5.26
Blacksmith	5.15
Blacksmith Helper	4.21
Muckers	4.47
Air Compressor Engineer	4.10
HAMMER WORK	
Chargemen	$5.26
Hammermen	4.94
Muckers	4.47
Blacksmith	4.94

The above rates are based on an eight-hour day.

The rates of May 16, 1916, were as follows:

Occupation:	Rate Per Day	Rate Per Week
SHAFT WORK		
Chargemen	$4.10	$24.57
Machine Runner	2.28	19.66
Machine Helper	2.73	16.38
Muckers	2.63	15.75
Blacksmith	3.41	20.48
Blacksmith Helper	2.47	14.81
Topman	2.10	12.60
TUNNEL WORK		
Chargemen	$4.04	$24.26

EDITORIALS

Forecast: Colder Weather and Trouble

THE shortening of demand for coal makes the operator careful. As soon as he hears of it he reacts to his fears and gives orders accordingly. Doubtless operators everywhere have issued orders to their managers calling for the laying off of all men whenever the mines are idle.

There is room, of course, for some reduction in the employment of labor. Last winter men were given jobs on idle days just to prevent them from straying away to other mines and other industries. The need for such "mark time" jobs is now ended. The only orders which now stand are "parade rest" or "forward."

Though this is true there is no reason why preparation should not be made for the winter. Whether the mines work steadily or slackly the winter must be faced. Steam lines will be excessively wasteful of power if not protected. Men will be injured by falls on the unprotected stairways of tipples. Shafts will fill with ice if falling water is not taken care of.

Drifts will close if the timbering is not properly protected by ditching away springs and by adequately covering the entry with properly sloped material. Cars will leave the tracks if the tracks are not jacked up to grade—a piece of work that can be done now with difficulty and can not be done at all when the frost has struck deep. Gondolas and hopper cars will stall on the railroad tracks if those tracks are not maintained at the proper grade.

Switches will continually be filling up with ice unless they are kept high so as to make the water run from them instead of toward them. Where the banks of tramroad and railroad cuts have been allowed to fall till the talus reaches the ties, and even the rail, they should be cut back and the ditch restored. Where slack and rock banks slope down in like manner they should be trimmed to line. Where the track is likely to be heaved by frost the ditches may still be made, or, if already made, cleaned.

Motor-truck roads which are too badly tilted for safe travel in icy weather should be regraded so as to make haulage safe. Water lines which may freeze should be covered, this being only more necessary when less water is used than it is when the full supply is being drawn on. In some places snow fences may be needed, and, where needed, should be erected.

Air stoves should be installed or built near outside pneumatic pumps. Drain valves and traps should be inserted in air lines wherever trouble from congealing water has been found in previous winters. Where water should be shut off over night and the pipes drained facilities for so doing should be provided.

Now is *not* the time for doing these things. They should have been done before; but better now than when the below-zero weather comes and stays and makes it impossible or immensely difficult to do them. We have had a labor shortage which has delayed necessary work. Until just lately we have had no "mark-time" jobs and have given no man work which could be delayed. Then came two or three weeks when no man wanted to work if he had a chance to celebrate. Consequently, there are many of the winter needs unprovided. Before it is too late let us perform the necessary work. With judgment in buying only such labor as is actually needed, the work will pay 100 per cent. on the expenditure before the winter is over.

A Mistaken Idea

MANY purchasers and would-be purchasers of coal-mine equipment throughout the country have doubtless been much chagrined during the past several months by the poor service rendered or promised by manufacturers. It is doubtless true that many buyers have felt that in this the manufacturers are at fault—that they have taken on war business to the utter disregard of old customers simply because war business promised bigger returns.

Such a charge, however, would in the vast majority of cases be entirely unjust. The manufacturers who have put their plants upon a 100 per cent. war basis have done so because this was necessary and practically demanded by the Government. Most manufacturers much dislike to be unable to serve old customers and thus retain their business and goodwill, and it has been a decided sacrifice upon their part to place their entire output with the Government.

The past year and a half has, however, been a time for sacrifice by everyone—producers and consumers alike. Fortunately, such sacrifices have now borne abundant fruit—Prussianism has received its just reward.

Scattering What We Have Garnered

A SHORT-SIGHTED policy seems to be in effect in many of the Government bureaus at the National capital. Called into existence to function for the public good, a number of little boards that have been operated at the expense of the people since our entry into the war now refuse to release for general dissemination facts and statistics that it is no longer necessary to keep hidden. During the war it was generally conceded that the publication of certain information would give aid and comfort to the enemy, and newspapers and periodicals patriotically refrained from printing such matter. Now, however, the situation has changed. The war is over, and there is no longer any need for secrecy.

At considerable expense, and at much inconvenience to industry as a whole, various data relative to conservation, consumption and like subjects, have been accumulated by the Food and Fuel administrations, the Federal Trade Commission, the War Industries Board

and a number of others. With the declaration of peace a number of these bureaus will cease to exist. What is to become of the vast collection of vital statistics now cluttering the files of these bureaus?

Reports that reveal the most intimate details of a number of industries were compiled because of the national emergency. These reports were digested by Government-employed statisticians, and averages, ratios and comparisons were deduced. The final figures, in a great number of instances, preach veritable sermons of efficiency and inefficiency. They indicate that competitors in a given industry, with the same overhead and general conditions to meet, arrive at widely different cost totals. Figures and facts such as these should be released immediately wherever such relinquishment will work no harm to an individual or to an industry, so that the lessons they contain be taught to those most interested.

During the reconstruction period now confronting the country it is just that the frankness shown by industry in throwing open its books for the national welfare should be reciprocated by the broadcasting to industry of the data collected by the nation. Boards and officials should be shorn of the power to withhold such information when it is asked for by accredited interests or the recognized organs of an industry. This broader concept of the rights of the public should light on all Government officials at once, before the documents have been filed away in some musty vault, never again, perhaps, to see the light of day.

To Increase Production of Anthracite

HITHERTO the bulk of the effort of the Fuel Administration in boosting production has been made in the bituminous regions of Pennsylvania and West Virginia. The anthracite region was not touched. In that region the companies were conducting such an admirable campaign that Federal assistance was not so urgently needed as in the bituminous coal areas. Though the production manager of the United States came from the anthracite region, he spent most of his time in the bituminous, where he felt the greater need existed and where a dire shortage probably would have continued to exist had the war not come to an end.

Influenza, celebrations and the loss of the war appeal have caused a lowering of the output in the anthracite region. The energy of the population has declined. So far as that is due to the lack of the war impulse, it is not logically excusable. Anthracite never was a part of the sinews of war. True, the production was hampered by exigencies of the military situation, the shortage of labor being a problem arising out of the war; but it was only indirectly a military problem, for anthracite coal supplied not a military but a civil need.

Then again the influenza and the peace-making celebrations both arose out of the war. Thus the war has interfered with the anthracite industry, while the civil need for coal is as large as ever, and that need is right at home. Very properly New York was last served with coal. Its needs were last filled because it was near the mining fields and therefore less likely to be cut off. But that left the burden of supplying New York till the worst of weather, when freezing cars and barges and ice-burdened rivers would have to be dealt with. Then the influenza and celebrations came, and New York, which was apportioned the last share, began to wonder whether there was a whole share left—if the last slice to be cut would prove not to be there at all when the cutting of it was under consideration.

Canada, the West, and New England with its inefficient gateways, of which we have heard so much, have been supplied. New York is cold. Let us trust that J. B. Neale will use his strength and energy and persuasiveness to see that care is taken of New York's needs. The miners supplied themselves with coal some time ago. They feared they might be left unprovided. Now let them see what they can do for the metropolis.

It is pleasing to have Mr. Neale protest against a recent reference in *Coal Age* to his delicate health. He assures us that he is robust and able to work untiringly. On his abilities as a speaker and organizer and on his unflagging energy New York must place reliance. It is the last bridge left across the dark waters of cold, disease and discomfort.

Don't Apostrophize Progress: Achieve It

MOST of us admire progress and pay it tribute. We like to hear and read about new developments of every kind. But industry would never make much progress if all were only hearers and readers, and no one told what he himself had done or seen done.

Well does Frederick M. Crunden preach from the facade of the St. Louis public library: "Recorded thought is our chief heritage from the past, the most lasting legacy we can leave to the future. Books are the most enduring monument of men's achievements. Only through books can civilization become cumulative."

We do not need to look back to a remote past to realize the truth of Crunden's saying. A new method is planned today; it may be recorded tomorrow; and in a few days later it has been applied in some other place with some trifling modification. This new work once recorded, a third party develops what the second party has done, and the process, method or system receives a rebirth. It passes through mind after mind, and after many transmigrations it is so changed as to be a new method.

But if an idea is not recorded, it does not receive these further refinements, and it is almost certain to die. Human progress depends on the transference of ideas, and the man who keeps his ideas to himself to gloat over, loses the great pleasure which comes from seeing them spread out and encompass the earth.

Our national life will be progressive if we exchange ideas promptly. It will be sluggish if we keep our observations to ourselves. It shows little judgment to deplore slow progress, while doing nothing to speed it. Yet that is what most of us are doing. If you have an idea lay it in the pages of a journal that it may fall therefrom like the seed of a plant and germinate the whole country over.

An assumption is too often made that a practice or method is general and so not worth recording. Sometimes, of course, this assumption is fully borne out by the facts; but much good practice is quite local and even individual, and it is the part of the technical press to introduce it to the industry wherever the practice is not known.

Keep Step or We'll Never Reach the Goal

Labor and Capital, Industry and Commerce, are running a three-legged race. If they don't keep step each with his running mate, they are sure to fall down by the way.

DISCUSSION BY READERS

Iron vs. Wood Mine Cars

Letter No. 4—In reply to the inquiry relative to the use of iron or wood mine cars, which appeared in *Coal Age*, Sept. 26, p. 615, and asked for an expression of views from practical readers in regard to the relative utility of these two types of cars, in coal mining practice, permit me to submit the following:

Owing to the severe conditions encountered in coal mining, it must be expected that mine cars will vary greatly in respect to the details of their construction. The type of car employed, in any case, must conform to such conditions as the height of seam, nature of top and bottom, quality and use of the coal, dimensions of shaft, method of payment for coal loaded, and numerous other items that influence to a greater or less degree the design of a mine car.

Before a final selection of mining equipment is made, careful consideration should be given to the many aspects that bear on the economic and successful working of the property considered. The capacity, shape and dimensions of the mine car, the material entering its construction, kind of wheels, bearings and axles, lubrication and, finally the choice between a tight- and an open-end car—all have an influence on the selection of the equipment.

Three Types of Cars, Classified by Material Used in Their Construction

There are three types of cars in general use in coal mines. These may be classed, according to the material used in their construction, as wood, steel and a composite type combining both of these materials. Where wood mine cars are used in the Eastern and Southern coal fields of the United States, they are usually built of white oak, the bottom boards being 3 in. thick, and the side, flare, door and end boards 1½ in. thick. In the extreme west and northwest sections of the United States and Canada, the high cost of white oak makes its use prohibitive, and what is known as "Douglas fir" is used in the construction of wood cars. This timber, however, is not to be compared with white oak for that purpose.

Briefly stated the attractiveness of the wood mine car consists in its cheapness and the ease with which it can be repaired by unskilled labor. In coal fields where wood and labor are cheap, these cars are built in the mine shops and the necessary iron parts, wheels and axles are obtained from manufacturers. But, even so, the superiority of the steel or iron car is now being generally recognized, and the use of this material is rapidly supplanting that of wood, for the purpose named.

The advantages of steel or iron, in the construction of mine cars, may be briefly stated as follows: (1) For the same outside dimensions, the capacity of a steel car is from 10 to 20 per cent. greater than that of a wood car designed for the same service, and the height of the car can be cut down from 4 to 6 in., which makes it particularly adapted for use in low seams. (2) Less muscular effort is required to move the car. (3) The cost of maintenance is less. (4) Steel or iron will stand the severe usage, in mines, better than wood, and survive many wrecks that would reduce a wood car to splinters. (5) The car retains its form and does not droop at the ends like a wood car. (6) The car is tighter and there is a less loss of coal in transit.

Arrayed against these advantages, however, are the higher cost of the material, which may be 40 or 50 per cent. greater than that of wood. Owing to its lack of flexibility, an iron car may not ride the rails with the same ease and, when derailed, cannot be replaced on the track as readily as a wood car.

Sections Bolted Instead of Riveted Together

In the use of iron and steel, let me suggest that the car should be built in sections and fastened together with bolts rather than rivets, which will facilitate the replacing of a damaged section and the straightening of bent plates. At some mines, where steel cars are in use, a crib or cage is built of ties. This is made large enough to admit a car, which can then be straightened by means of jacks placed between the crib and the car. Trouble is often experienced when straightening a car, by reason of the end gate not closing properly, as it is difficult to secure the same alignment as before the damage was done. For this reason, I would advise the use of a steel or iron car having a tight end, wherever a rotary dump can be installed.

The use of iron cars in the working of thin seams greatly reduces the cost of brushing the roof or lifting bottom. Again, through careful investigations, made to determine the amount of muscular energy expended in the loading of coal into cars 32 in. and 52 in. in height, respectively, it has been found that the same muscular energy is required to load 29 tons of coal into the higher car as is necessary to load 44 tons into the lower car, under the same conditions. This furnishes food for thought and shows the importance of keeping the height of the mine car as low as possible, in order to secure the greatest efficiency in mine labor.

Steel Cars Used in Pitching and Thin Seams

In closing, let me say that my personal preference is for steel or iron cars wherever the price of the material is not prohibitive. In pitching seams, as well as in thin seams of coal, the use of the iron car is a practical advantage. At the McGillivray Coal and Coke Co.'s mine, at Coleman, Alta, Canada., which I assisted in opening, we had thirty 4¼-ton steel cars equipped with automatic couplers and belts. These cars gave every satisfaction and proved an ideal type to use in a pitching seam where a large tonnage is

produced and the workings are extensive. A car of this capacity, however, could not be used in a low seam or where the miner is required to handle his cars.

In 1909, while on a trip through the East, I visited some of the largest coal mines in Pennsylvania. At the Vesta, No. 4 mine, California, Penn., which was at that time the largest mine in the world, and shipped that year 1,668,822 tons of coal, the Watt steel mine car having a capacity of 3 to 3½ tons, depending on the way it was loaded, was in use. The foreman told me he had 2350 of these cars in the mine and they were highly satisfactory. It is worthy of note that this mine, producing 7000 tons of coal a day and involving most important haulage considerations, considered this type of car the best type to use. The fact should convince the most skeptical in regard to the utility of these cars.

Reducing Ventilation at Firing Time

Letter No. 1—In Technical Paper No. 190, recently issued by the Federal Bureau of Mines under its coöperative agreement with the Illinois State Geological Survey and the University of Illinois Experiment Station, facts are presented that are intended to prove that interfering with the ventilation of a mine at shotfiring time is a dangerous practice. The writers claim it has been shown by the results of tests made in the Bruceton mine, that retarding the circulation in a mine at such time is not preventive of dust explosions.

This practice had been condemned some time before, by men connected with the Bureau, and it seems remarkable that, notwithstanding the objections urged and their authoritative source, the practice of interrupting ventilation at shotfiring time has not only not been stopped, but has been steadily gaining ground.

Faith of Shotfirers in the Practice

It is even more remarkable that shotfirers still insist on the continuance of this practice if they are convinced that many dust explosions have occurred in mines as the result of the practice. It is unbelievable that men would deliberately continue to risk their lives by adhering to an alleged useless and dangerous practice, unless their personal experience and observation has taught them that its discontinuance would increase the hazard of their work.

I have talked with shotfirers from different mining states regarding this matter, and they agree almost without exception that the presence of a strong draft at firing time is highly dangerous. They expressed their conviction that its retardation or even the entire suppression of the air current has had a protective effect in the performance of their work. They were not particularly impressed with the arguments that have been urged against interrupted ventilation at firing time, and which are based upon the fact that an occasional explosion has occurred with the fan shut down.

The practical and experienced shotfirer regards the presence of flame as a potential menace and the primary cause of a possible explosion, whether the flame is that of a mine fire or a shot. It appears to him as inconsistent to claim that the draft must be cut off from the fire and not follow the same plan to reduce the chance of flame from a shot. The shotfirers with whom I have talked seem to fear the presence of draft and certain air conditions, at firing time, more than they do the presence of dust.

Inrush of Air Follows the Firing of a Shot in Mine Workings

In order to call attention to certain phenomena accompanying the firing of shots, permit me to refer to an article that appeared in *Coal Age*, Vol. 6, p. 623, over the signature "A Mining Engineer." The writer of this article is seemingly much opposed to the practice of interrupting ventilation at shotfiring time and makes the following statement: "All will concede that an inrush of air follows a shot and continues, in point of time, until atmospheric pressure has been reached," admitting, no doubt, that when the blownout shot is a large one, the inrush following is correspondingly large.

Allowing this to be true, it must then be conceded that, as an inrush of air follows the firing of every shot, such an inrush was undoubtedly present in every case where a dust explosion resulted from a shot as the primary cause; also, that the inrush of the dust-laden air took place prior to the start of the explosion and that therefore the injection of the dust and air mixture into the place where the shot was fired produced the first manifestation of explosive combustion.

"Mining Engineer" admits that the inrush of air following the firing of a blownout shot is generally greater than the inrush following a shot which brought down the coal. Should there be dust present, it is obvious that the greater the force of the inrush the more dust will be carried by it and injected into the remaining flame. In view of this and the further fact that blownout shots are the primary cause of many dust explosions, it is but reasonable to conclude that the magnitude of the inrush of the dust-laden air is a potent factor in determining the magnitude of the subsequent explosive combustion, and the employment of any artificial means that tends to increase the force and volume of this inrush must necessarily aid in increasing the scope and intensity of the explosive combustion.

Effect of Draft to Assist Ignition of Dust

Therefore, I insist that the restriction of artificial draft at shot-firing time, wherever existing conditions will permit the practice, must have some merit. There is, moreover, abundant proof furnished both by mine explosions and the result of laboratory tests to support this view. For instance, in Bulletin 425, issued by the Bureau of Mines, on page 133, under the caption "Significant Points in Experiments," we read as follows:

> It will be recalled, too, that Holtzwart and Meyer drew attention to the fact that no ignition was obtained if they introduced lignite dust into their apparatus and, after establishing the spark between the terminals within, disseminated the dust in the air by shaking the tube. But when the dust was puffed between the terminals by compressed air ignition occurred.

In view of this fact it would seem that better proof than has yet been given should be submitted if it is desired to show that the presence of artificial draft can

have no part in promoting explosive combustion. The fact that explosions have been produced, in the Bruceton experimental mine, with the fan shut down, only serves to show that the inrush of air, due to the vacuous condition caused by the cooling of the gases from the shot, was of sufficient force and volume and sufficiently dust-laden to produce explosive results when it came in contact with the remaining flame.

The practice of restricting ventilation at firing time may have its drawbacks and shortcomings and, if so it is right that they be pointed out; but the existence of such hindrances should not be used to create the impression that the theory on which the pratice rests is unsound, especially in the absence of any proof to that effect. In my judgment, the surest and quickest way to dispose of the controversy regarding draft restriction and, at the same time, make real progress toward the solution of the dust-explosion problem is by definitely establishing the fundamental principles involved in the production of explosive combustion.

Air Factor vs. Presence of Fine Dust

If the engineers connected with the Bruceton experimental mine can produce proof that explosive combustion of mine dust is effected by some such means as, say conductivity or radiation, then it must be conceded that the presence of dust is the all-important thing, and that the air factor plays but a small part in the process of explosive combustion, in which case restriction of ventilation at shotfiring time would have no value whatever. But, until that proof is forthcoming, the claim of the potency of the air factor should receive careful consideration.

The claim for the air factor is based on the theory that explosive combustion of dust is obtainable only with the assistance of a draft of sufficient force to carry the dust in suspension and the dust-laden air is injected into a heated zone having a temperature at or above the ignition point of the dust. The process is similar to that by which coal dust is burned with almost explosive effect when injected by a blast of compressed air into the combustion chamber of a furnace. If it can be shown that this is the correct view then draft, both as a fuel conveyor and in its flame-supporting capacity, must be regarded as a most potent factor in the development of explosive combustion, and consequently every available means, tending to lessen its harmful effectiveness, and permissible under existing conditions, must be employed if dust explosions in mines are to be avoided.

Chariton, Iowa. Former State Mine Inspector.

Mine-Rescue Work

Letter No. 4—The discussion of mine-rescue work, in *Coal Age*, by practical men who have had experience in wearing breathing apparatus under working conditions, should be both interesting and instructive. I am sorry to say that some people, even mine superintendents and managers, have the idea that when a man dons a breathing apparatus he can do anything and everything. It is needless to say that temperature and other conditions are not considered where such statements are made by those not acquainted with mining conditions.

On one occasion when I and others who had trained in the use of breathing apparatus were called to a certain mine, we experienced just such a condition as that to which I refer. The men at the mine had been led to believe, from the talk of the mine officials, that something wonderful was to be pulled off by the men wearing the apparatus. A sort of Barnum & Bailey exhibition was expected. There was nothing, in their belief, that mine-rescue men could not do. As a result, when the miraculous did not appear, the men ridiculed our work and failed to appreciate the real value of such means of rescue.

Wearer of Apparatus Must Study Its Construction and Limitations

Let me say that, before a man or any set of men, put on an apparatus designed to permit them to work in an irrespirable atmosphere, the construction of the apparatus must be carefully studied. The wearer of the apparatus must be thoroughly familiar with its use and the limitations of the work of rescue under such conditions as they meet in the mine.

Temperature is a most important item and must govern and control all work, in the wearing of breathing apparatus. According to the gas chart issued by the U. S. Bureau of Mines, showing the effect on man of warm, moist and still air, it is stated:

> A hot, moist atmosphere prevents the evaporation of perspiration. If the hot, moist air is stationary it becomes entangled between the clothing and the skin and becomes warmed to body temperature. Hence, the body can not lose heat to the air, and the skin becomes warm, flushed and bathed in perspiration. Setting the air in motion, by a fan, whirls the hot air away from the body and allows cooler air to take its place. Hence, arises the beneficial effects of a fan in a room, even if fresh outside air cannot enter. If the wet-bulb temperature of the air is the same as that of the body, 99 deg. F., the body can not lose heat; but if the air temperature is about 70 deg. F. perspiration can evaporate. Above 75 deg. F., wet-bulb temperature, the amount of work a man can do begins to fall off. Between 80 and 85 deg. F., wet-bulb temperature, hard continuous work is almost impossible. Wet-bulb temperatures are determined with a sling psychrometer.

There is little doubt but that the data given in this statement are the results of exhaustive experimentation by the Bureau of Mines. The facts brought out in the statement should be studied by all men who may at times be called upon to wear apparatus in an irrespirable atmosphere. The most careful attention should be given to the study of these facts, by all men in charge of rescue teams.

Precautions To Be Observed by Rescuers

Allow me, here, to give a word or two of advice, in line with my own experience in the wearing of apparatus in the mines of southern Illinois. First, let me urge all mine rescuers to consult with the state mine inspector or the mine management, before entering upon the tasks or duties to which they are called. It will generally be found that these men will not dictate what the rescuers should do, but will confer with them in an attempt to ascertain the best method to adopt in the interest of all concerned.

Again, where men have traveled some distance to a fresh air base, or have exerted themselves in any manner, let them rest for 10 or 15 min., until their breathing becomes normal, before attempting further efforts

with breathing apparatus. A man in charge of a crew should have them under his continual observation and never permit them to overexert themselves.

This constant watchcare of the leader will enable him to detect any signs of distress or weakness on the part of one of his men. It will, also, give the men greater confidence in themselves when they know that their movements are closely watched, and they will be less liable to become nervous, which always causes weakness. Where a man becomes nervous when wearing apparatus, his fearfulness and dread lead to weakness, and he is sure to collapse before long. Then, where one man in a crew collapses the entire crew is apt to be disorganized, because the same fear and dread takes possession of the others.

In conclusion, my advice is let mine rescuers pay little or no attention to what inexperienced men say, even though they are the mine officials in charge of the mine. If they are not acquainted with the use of breathing apparatus, they are not capable of giving advice to rescuers who wear such apparatus. Every man of a rescue team must depend wholly on his own nerve and the advice of his leader who is in charge of the team and whose duty it is to see that every precaution is taken to safeguard his men.

JAMES WEIR, Supt.
Mine-Rescue Station.
Benton, Ill.

Perplexities of Mine Foremen

Letter No. 3—Reading the short editorial entitled "Seeing the Boss Wastes Time and Temper," *Coal Age*, Oct. 24, p. 791, brings to my mind more forcibly than ever some of the many perplexities of mine foremen, which subject I am glad to see has been recently brought to the attention of writers in the Discussion department of the paper.

Permit me to say that the writer of the editorial to which I have referred, either from lack of experience in bossing in coal mines, or for a lack of space to discuss the situation more fully, has viewed the matter from one side only. There is a class of miners who put in more time looking for the boss than they do in working their places. There are miners who are continually looking for the boss and running to him with every little frivolous thing that the better and more efficient miners would settle for themselves.

Common sense and judgment should lead a miner to adjust those little matters and difficulties with which he knows he must contend in the mine, and not bother the boss who has business of far greater importance that requires his constant attention. As I said, there is a certain element in miners that makes too many of them ready and willing to leave their working places on the slightest pretext and wander about the mine looking for the boss. They are often only too glad to have an excuse for leaving their places.

A long experience as a miner and acting in different capacities in charge of mining work has made it clear to my mind that the average mine foreman is always ready and willing to listen to the complaints of miners when they are sincerely and honestly made. A good foreman is quick to learn the character of those miners who continually worry him with little matters that they should adjust themselves. It is well known that the impracticable methods employed by many inexperienced miners serve to keep their working places in an unfit condition.

A good boss is familiar with the local conditions in every miner's working place and knows that it is not necessary for him to go to many of these places every time he is asked. For this reason, he frequently pays little attention to a miner's request for him to look at his place. He knows the conditions he would find there and knows that the miner has not taken proper precautions to avoid his troubles. The whole time of the foreman could be taken up visiting such places and, in the end, little or nothing would be accomplished.

Much Is Expected of Mine Foremen

Referring again to the editorial mentioned, I cannot agree with the impression it conveys that bosses are "anxious to avoid an interview" with miners who need their advice and assistance, except under conditions such as I have described, when the mine foreman knows too well that it would be a waste of precious time. In my experience, not many foremen will delay answering a call to go to a place they know needs attention.

In speaking of the perplexities of mine foremen, the fact has been demonstrated that these officials have troubles of their own. Many things go wrong about the mine and conditions arise that make it almost impossible to get rails and props to working places as quickly as the miner thinks they should come. On this account, a miner may often be obliged to cease work until the needed material can be sent to him.

Today, when large results are expected, the foreman's attention must be given first to the more important matters required to keep the mine safe and the coal moving. A motor has broken down, a haulage rope needs to be repaired, a broken rail replaced in the track, or a fall of slate cleaned from the roadway.

Any of these things if not given immediate attention will seriously affect the output of the mine. On the other hand, a little water in a miner's place means only the loss of a few tons of coal if the miner cannot work that day because he is drowned out of his place. Of many evils hindering the production of coal, the foreman must choose the least and give his attention where it is most needed.

Needless Complaints of Troublesome Miners

There are some miners who appear to think that the boss must look after their little troubles at once, even if he has to neglect the general and more important things of the mine. Many miners are impatient and unreasonable and quickly manifest a spirit of discontent, giving some trivial excuse for leaving their places or quitting their work in the mine. They are prone to recite their grievances to outsiders, particularly to men who are unfamiliar with mining conditions and requirements and who are easily led to believe that the miner is not treated fairly by the boss. But, in the great majority of cases, it can be said that the miner has proved trifling and troublesome and the boss is only too glad to get rid of him. As a general rule, the outsider is more ready to listen to such complaining miners than to the more conservative class.

In summing up, let me say that the average mine foreman, today, is a very busy man and can ill afford to give his time to needless complaints from miners who

are no more satisfied after the boss has done everything possible for them. The foreman has every class of inexperienced and irresponsible labor to deal with in the mine. Why then refer to him as "that dignitary," or insinuate that his time is much taken up in keeping out of the way of his men.

I am convinced that the majority of mine bosses are neither autocratic nor cowardly in dealing with their men. The best foremen are themselves experienced miners and know the difficulties the miner must meet every day. Notwithstanding his many perplexities and responsibilities, however, the foreman must keep cool and pleasant.

Rather than regarding it a great waste of time and temper on the part of the miner who must wait for the boss to come to his place or hunt him up in some part of the mine, it should be considered a greater waste of time and, possibly, temper when the boss is required to go to any remote place in the workings whenever and wherever he may be called to adjust a little matter that is in the miner's own control. JOHN ROSE,

Dayton, Tenn. Former District Mine Inspector.

Hindrances to Coal Production

Letter No. 6—I have just read the interesting letter of Joseph R. Thomas, *Coal Age*, Oct. 10, p. 710, which impressed me with the thought that if the mine officials of a company did not show favoritism of a certain kind they would be the losers. Many of their best men would be seeking work where their efforts would be recognized and rewarded. I am speaking now of the deserving ones, and do not refer to the shiftless class who are often found hanging around a mine and depend largely on the "pull" they have with the foreman.

In every well managed mine there are those who are the favorites of a good foreman. These favorites are the men who have come into the community to stay. They are men of families. In most cases, they rent company houses and trade at the company store; but they are the men who work six days in the week and produce their share of coal.

THE TRUE FAVORITES OF A GOOD FOREMAN

Is it any wonder that a mine foreman takes good care of this class of workers, gives them good places and treats them with consideration? Such treatment is only their due reward for good work and for acting in the interests of the company, which so large a class of miners fail to do but, instead, regard their own interest and convenience first.

Let me ask, again, is it strange that a foreman makes a favorite of a married man, when he knows he can depend upon him more than on a single man who is free to come and go as he may choose? Does not good management require that a foreman do this, in order to insure a steady production of coal and maintain a large output for the mine? The best workers and most reliable men should be a mine foreman's favorites.

It would, of course, be foolish for a mine foreman to decide that he would have no favorites in the mine, but would treat every man alike. For instance, suppose he should let a good place stand idle, waiting for the next man who might come along, who would probably be a tramp miner. Should such a man be given the place after it was refused to one of the old miners when vacated a few days since, would not such treatment cause dissatisfaction? No one would blame an old miner who was refused the place, if he decided to pick up his tools and go elsewhere. As soon as the tramp miner had made his stake, he would be "Johnny on the road" to some other place.

While the favoritism described by Mr. Thomas is truly a hindrance to the production of coal, there is another hindrance that he does not mention. The wages paid, today, for company labor in and around the mines, is excessive as compared with the earnings of a man who digs coal and has his family to support. For instance, a mule driver is often a single man. He is paid $5.25 per day, and his board costs him $1.30 per day. He generally works four days out of the week, and the foreman must look for someone to fill his place the remaining two days. The high wages paid this man is actually a hindrance to the steady production of coal.

Numberless schemes have been devised and tried for keeping a man at work in his place. It has been found a practical impossibility, however, to compel a man to work when he wants to lay off. If a miner wants to lay idle Saturday he simply does not prepare his coal, and that lets him out. All plans to overcome this difficulty have seemingly failed.

INDIFFERENCE OF MINERS HINDERS PRODUCTION

In one instance, a miner was threatened with discharge if he did not load more coal. It made no difference to him, however, as he continued to load his six tons by noon and then lay idle or asleep in the gob until quitting time. Another miner was out three days and claimed he was sick. The foreman told him to get a doctor's certificate and he did so; but the real trouble was the whiskey bottle. Being discharged, he went to work in another mine where he did the same thing again. If it were not for these hindrances, the production of coal, today, would far exceed the demand. It reminds me of a book that I once read, in which the writer likened the laboring man to a mule, claiming that he would only work when he was hungry.

Let me sum up by saying that, in my opinion, the average man working under pressure will perform work with the least possible resistance; but, as the load is increased, the circuit breaker flies out and he ceases his activity. In face of these conditions, let me suggest that every mine should be operated on an ample margin. For example, if an output of 1000 tons a day is needed, the management should estimate on 1200 tons and, perhaps, they will realize the tonnage first named. If a miner loads 12 tons of coal a day, estimate his average as 10 tons a day, and this will require that the mine work 100 men to produce 1000 tons daily.

As a fact, the coal miners of America, today, have realized that we were at war, and they were ready to do a day's work. Notwithstanding all the hindrances that we can mention, the demand for coal has been met at the mines. The President has gotten what he asked and 2,000,000 soldiers are in France today, while the people at home have subscribed $6,000,000,000 for the support of the war, which gives the assurance that our boys will go into Berlin and land the Kaiser and all his murderous tribes on St. Helena.

Farr, Colo. ROBERT A. MARSHALL.

INQUIRIES OF GENERAL INTEREST

Freezing of Shaft in Winter

During the past four or five years it has been necessary to shut down our mine from three to five days each winter, owing to the air shaft freezing solid with ice. At the present time, it does not seem possible to attempt to shut off the water, which enters the shaft at a point approximately 70 ft. below the surface.

Seemingly the only alternative is to heat the intake air to a temperature above the freezing point, at times when that is necessary. In order to do this we are contemplating installing a series of steam coils, arranged in such a manner that the intake air will be drawn through the coils before reaching the fan, which is now forcing 50,000 cu.ft. of air per minute down the air shaft. We expect to heat this air from 20 deg. below zero to 40 deg. above.

As this proposition is an important one to us and will, no doubt, interest others in a like situation, will you kindly state if it is possible to accomplish our purpose in the manner proposed. It would please us to see the matter discussed in *Coal Age*, which we are sure will bring out many helpful suggestions.

———, Ill. GENERAL SUPERINTENDENT

The heating of a large volume of intake air, by passing it over steam coils, would require a considerable distribution of the air at that point in order to enable it to absorb sufficient heat to produce the given rise of temperature (60 deg. F.). The practicability of the scheme must be determined by a calculation based on the amount of heat that must be absorbed by the volume of air to produce the desired rise in temperature, and the possibility of the air extracting this heat from the steam in the coils. Also, it will be interesting to estimate the weight of fuel burned under the boiler.

The weight of 50,000 cu.ft. of air, at a temperature of 20 deg. below zero, would be 50,000 $\times$ 0.0903 = 4515 lb.; or, measured at a temperature of 40 deg. F., the weight of this volume of air is practically 4000 lb. The specific heat of air, at constant pressure, is 0.2374, which is the amount of heat (B.t.u.) required to raise the temperature of 1 lb. of air 1 deg. F. Therefore, the heat required to raise 4000 lb. of air 60 deg. is 4000 $\times$ 60 $\times$ 0.2374 = 56,976 B.t.u., which is the heat that the air must absorb from the steam coils each minute.

Assuming the steam pressure in the coils as, say 10 lb. gage, the heat in the steam, above 32 deg. F., at sea level, is practically 1155 B.t.u. per lb. Then, if the arrangement is such that the air passing over the coils condenses the steam and extracts enough heat to reduce the temperature of the condensed mater to, say 87 deg. F., which is hardly probable, the heat given up by a pound of steam would be 1155 + 32 — 87 = 1100 B.t.u. On that basis the weight of water evaporated or steam condensed—in other words, the *capacity* of the steam plant employed for this purpose—would be 56,976 $\div$ 1100 = 51.8 lb. per min., or practically 12½ bbl. per hour. The conditions assumed in this calculation are probably more favorable than would be realized in practice, and double or triple this evaporation may be found necessary.

Taking the efficiency of coal burned under a boiler as, say, 7 per cent., each pound of coal having a heating value of 14,000 B.t.u. per lb. would yield 14,000 $\times$ 0.07 = 980 B.t.u., which is the heat available in each pound of coal burned. The weight of coal that must be burned per hour, in this steam plant, to meet the requirements is then 60 (56,976 $\div$ 980) = 3488 lb., or say 1¾ tons.

The foregoing calculations show that the proposed scheme is, at the best, not practicable. The necessary distribution of the intake air over the coils, in order to permit such a large volume of air to absorb sufficient heat to raise its temperature 60 deg., would necessitate either a very large area in the fan drift, so as to reduce the velocity of the passing air and give it time to absorb the necessary heat, or baffle plates would have to be inserted to give the air current a devious course among the coils. The first of these plans presents practical difficulties that cannot be surmounted in most instances, while the second would greatly increase the drag on the air, or the resistance against which the fan must operate, and would reduce the air volume in the mine for the same power of the ventilator.

The simplest and most practicable scheme for preventing the freezing up of a wet air shaft, in winter time, is to reverse the circulation in the mine. This must be done at alternate intervals, wherever and whenever that is practicable, so as to prevent the freezing up of the hoisting shaft while thawing out the air shaft, and *vice versa*.

The difficulty presented in this inquiry is not an uncommon one. On the contrary, it is one of frequent occurrence with which the coal-mining industry has long contended. *Coal Age* will be glad to have its practical readers discuss the question broadly, giving their experiences and suggestions.

Has anyone ever tried a method of impregnating the water draining into the shaft with salt? Or what might prove more practical, spraying a brine solution over the ice formed in the shaft? A 25 per cent. brine freezes at zero (Fahr.). The application of any such scheme would involve the shipment to the mine of a carload of rock salt from the salt mines.

In the use of salt for the purpose mentioned, a more effective scheme to adopt, wherever practicable, would be to cut through the curbing at a point just below the inflow, and establish a water-ring surrounding the shaft. A steam coil introduced into this space would effectually prevent the freezing of the water, which should be drained from that point to the bottom of the shaft. Or, a pump installed at this point would effect the double purpose of preventing freezing and elevating the water to the surface. Let us have opinions, or better still, the results of experience of readers.

EXAMINATION QUESTIONS

Miscellaneous Questions

(Answered by Request)

Ques.—A horsepower of 8 produces 60,000 cu.ft. of air per min., in a certain mine. What will a horsepower of 27 produce in the same mine, under the same conditions?

Ans.—In mine ventilation, the quantity of air in circulation varies as the cube root of the power on the air. In other words, the quantity ratio is equal to the cube root of the power ratio. Therefore, calling the required volume of air x, we have, in this case,

$$\frac{x}{60{,}000} = \sqrt[3]{\frac{27}{8}} = \frac{3}{2} = 1.5$$

$$x = 60{,}000 \times 1.5 = 90{,}000 \text{ } cu.ft. \text{ } per \text{ } min.$$

Ques.—Explain the nature and cause of priming, in a steam boiler.

Ans.—The term "priming" in relation to a steam boiler means the carrying over of water into the steam pipe and cylinder of the engine. Priming may occur from any one of several causes, among which may be mentioned too high a water level in the boiler or too small a steam space, due to the improper design of the boiler. Priming may result from forcing a boiler, because of insufficient boiler power; it may also be caused by irregular firing, or the sudden opening of stop-valves. Priming may result from violent foaming in the boiler, caused by impure feedwater or the accumulation of grease and sediment in the boiler.

Ques.—Explain the reasons why a boiler feed pump will force water into a boiler when the steam pressure in the boiler is the same per square inch as that actuating the pump.

Ans.—The reason is that the steam end of the pump has a greater sectional area than the water end or plunger, which gives a greater total pressure acting on the steam piston than the total pressure exerted at the water end, against which the plunger operates. For example, assuming a 2-in. plunger operated by a 6-in. steam cylinder, since the areas of the plunger and piston vary as the squares of their diameters, the steam pressure in the cylinder will overcome nine times that in the boiler.

Ques.—How many 3-in. pipes will be required to run off as much water as one 12-in. pipe, all the pipes being of equal length?

Ans.—For the same head of water producing the flow in these pipes, all of which have the same length, the quantity of water that will flow in each pipe will vary as the square root of the fifth power of its diameter. In other words, the quantity ratio is equal to the square root of the fifth power of the diameter ratio. The diameter ratio, in this case, is $12 \div 3 = 4$. Then, calling the flow in one 3-in. pipe 1, or unity, the flow in a 12-in. pipe, under the same head, will be $\sqrt{4^5} = 32$. Therefore, one 12-in. pipe will carry 32 times the quantity of water flowing in a 3-in. pipe, under the same head; and it will require thirty-two 3-in. pipes to run off the same quantity of water as a single 12-in. pipe, all the pipes having the same length and the same head.

Ques.—The elevation at the head of a slope is +900 ft.; the elevation at the foot of the slope is +300 ft.; the length of the slope is 1200 ft.; what is the degree of pitch of the slope?

Ans.—The vertical rise of the slope, in this case, is $900 - 300 = 600$ ft. Since the length of the slope is 1200 ft., the angle that the slope makes with the horizontal, or the slope angle, is one whose sine is $600 \div 1200 = 0.5$. From a table of sines and cosines, this angle is found to be 30 deg. The slope has, therefore, a 30-deg. pitch.

Ques.—What are the principal things to be looked after on haulage roads in mines?

Ans.—A haulage road in a mine should be as straight as possible. The track should be well ballasted, the roadway drained and timbered so as to prevent falls and give sufficient headroom for the passage of cars. The grade of the main road should favor the movement of the loaded cars, the most economical grade being from 1 to 1.5 per cent. There should be a good clearance space on the same side of the track, for the entire length of every haulage road. Where mechanical haulage is employed, there should be refuge holes cut in the rib on the same side of the track. These holes should be whitewashed and kept free from all obstruction, so that they can be quickly found when needed.

No doors should be permitted on a main haulage road in a mine. As far as practicable, doors should also be avoided on cross-entries. A door should never be erected at the foot of a sharp grade. There should be no sharp curves that would cause the derailment of a car. Where turnouts are made on haulage roads, they should be timbered without necessitating center posts between the tracks. A block or other device should be employed to prevent cars from running out onto the haulage road either from turnouts or from rooms. All switches must be well laid by good tracklayers and guard rails used to prevent cars from jumping the track when crossing a frog.

Ques.—What gases are produced by mine fires and the explosion of firedamp?

Ans.—The principal gases produced by mine fires are: Carbon dioxide (CO_2) and carbon monoxide (CO), depending on the quantity of air supplied by the fire. The explosion of a firedamp mixture, at its maximum explosive point, produces carbon dioxide (CO_2) and water vapor (H_2O). A firedamp mixture when exploded below or above this point will produce more or less carbon monoxide, and there may be some unburned marsh gas (CH_4) remaining after the explosion. In any combustion, there is always some free nitrogen remaining in the burnt air; more properly speaking, there is an excess of nitrogen in the air, following an explosion.

COAL AND COKE NEWS

Harrisburg, Penn.

The claimant is entitled to be judged dependent upon the contributions of a deceased child, if these contributions have been necessary to support, interpreted in accordance with the station of life and manner of living of those who assert such dependency, says Chairman H. A. Mackey, of the State Compensation Board, in a new decision regarding what constitutes a parent's dependency rendered in Mickano vs. Rochester and Pittsburgh Coal and Iron Co., "It might be shown that the child's contributions to the family purse had been necessary to maintain other members of the family in school or to furnish musical instruction to other members, or to maintain an automobile or to obtain other very proper luxuries which cannot be included in the category of actual support. We do not think that the Legislature intended that the employer should pay compensation in order to secure these items for the home."

A meeting of the State fuel administration and anthracite coal operators was held in Philadelphia, on Nov. 18, with the purpose of bringing about a larger distribution of hard coal in certain states. Dissatisfaction was expressed with the present amount of distribution. Among the states represented were South Dakota, Minnesota, Wisconsin, Indiana, Pennsylvania, Delaware, New Jersey, Connecticut and New Hampshire. Others at the meeting included J. D. A. Morrow, director of distribution of the United States Fuel Administration, and J. H. Dickson, New York; S. D. Warriner, and W. J. Richards, who constitute the anthracite committee of the National Fuel Administration.

It was explained by anthracite operators that the October production was 800,000 tons short of the same month last year, which affected the distribution in all states. This loss in output, it was said, was due to the influenza epidemic and other causes. The operators explained the situation to the state administrators and suggestions were offered looking toward a greater supply of coal to communities before severe weather sets in.

Uniontown, Penn.

Conferences of team-track coal operators with Fuel Administration officials at Washington brought no relief to that industry, threatened with extinction by the railroad order substituting open-tops for box-cars. The committee was told that the box-cars were needed for the shipment of grain, but were not given any assurances when such cars would be returned to the coal trade. The two classes of cars means a difference of 75c. per ton and the operators claim they cannot do business with a profit at the open-top fixed price of coal. In the party which went to Washington were J. D. Madigan, of Connellsville; M. Lee Titus, of Point Marion; J. C. King and J. H. Dunn, of Uniontown, officers of the Team Track Operators' Association, with their attorneys, Lee B. Brownfield and John Duggan.

Flare-up of influenza in malignant form generally throughout the Connellsville coke region reduced production of coal and coke to another low level for the week ended Nov. 16. Reports compiled at the regional fuel administration office give a total output of 573,576 tons of coal, with an aggregate loss of 37,018 tons over the previous week. Coke shipments were 258,224 tons, a drop of 19,625 tons. Coal shipments were 219,837 net tons, showing a decrease of 64,725 tons.

While there was some car shortage for the week the principal difficulty was labor shortage. Influenza has now taken hundreds of workers from mines and yards which were heretofore not affected by the disease. Their withdrawal, together with the large number of convalescents not yet able to work full time, present a grave labor problem, which however, can be but temporary. The analysis of the week's production by the fuel administration places labor shortage as responsible for the loss of 5676 cars. Car shortage itself caused a loss of 1161 cars. Cars shipped during the week were 9817 with a rating of 16,372. Loaded coke cars to the number of 6936 left the regions while 2881 cars of coal were shipped to byproduct plants and other industries.

Charleston, W. Va.

During the week ending Nov. 16 the Fairmont region received a full supply of cars, the allotment running from 1500 to 2000 cars a day. One day's supply reached 2900. There were evidences, however, of delay in placing the cars. Production loss was reduced to a minimum, not running over 1000 tons a day. A few of the mines were shut down during the week. Even team-track mines were able to secure an adequate car supply, and open-top cars at that.

Production is still running below normal in the Pocahontas and Tug River regions, due to a pronounced labor shortage. The total output, according to the last compilation, is only 415,000 tons, or an increase of 3000 tons only over the previous week. The total production loss reached 62,452 tons, 52,531 tons of which was due to labor shortage. Five thousand more tons of coke were manufactured than during the week previous, the total production being 53,251.

Notwithstanding an extremely poor power supply in the New River district during the last two weeks, there was a very material increase in production in that field during the period ending Nov. 16. The total output was 139,811 gross tons, representing a gain of 13,597 gross tons. As an instance of the conditions with which New River mines have had to contend, last Thursday was entirely lost, and during the current week there was insufficient power on Monday and Tuesday. The supply was off again on Thursday.

The mines in the Kanawha District managed to speed up production to 167,711 tons during the week ending Nov. 16, thus gaining about 5000 tons, over the previous week's production. Power shortage and a scarcity of man power handicapped operators. Only ten hours were lost from car shortage, but from a shortage of labor there was a loss of 1016 hours. A loss of 908 hours from mine disability shows to just what extent inability to get power held down the output.

As all western shipments of fuel from the Kanawha and Guyan districts are required to be rebilled at Russell, Ky., and as there were reports of the blocking of tracks there, the possibilities are that western shipments would be halted and that a number of mines might have to shut down.

Birmingham, Ala.

Coal and ore production of this section has almost returned to normal. The production of coal for the week just closed is expected to show at least 10,000 to 20,000 tons increase over what it was for the week ending Nov. 9, when 348,306 tons were recorded by the Federal Fuel Administration offices here.

The hope is expressed that the output of Alabama mines can be increased to more than 400,000 tons weekly early in December, although it is thought unlikely that 433,000 tons mined in July will be surpassed, due to the unfavorable weather conditions which in all likelihood will be experienced throughout the district at the beginning of the winter season.

There is urgent need for every ton of coal that can be mined in the entire district. Domestic orders in large numbers are yet to be filled, while industrial plants, railroad lines and steamships, negotiating the change from a war to a peace basis, will need coal and coke in steadily increasing amounts, as the commerce of the nation recovers from its war footing and begins to assume normal proportions.

There is optimism in the fact that many men, available for work in the mining district of the state, will probably be released from cantonments in this country in the next few weeks, and it seems reasonable to believe that the labor shortage which now is the bugaboo of every operator in the district will be alleviated.

It hardly seems possible that there will be any release of coal cars in the immediate future. Supplies will be shipped for Government use for several months to come, and there is not much chance of the mines in this district being furnished with additional cars, according to railroad officials in Birmingham.

New York, N. Y.

The directors of the Wholesale Coal Trade Association of New York have decided to establish a coal exchange in connection with the Association, following the submission of a report by a committee headed by C. C. Harris, of George D. Harris & Co. The report was discussed by a meeting of coalmen, including members of the Association and invited guests, held at the Whitehall Club, following the luncheon of the Association, and was adopted by the Board of Directors a few days later.

It is the purpose of the Exchange to promote better trade relations between members of the wholesale trade, to facilitate dealings between buyers and sellers, to provide a medium through which producers of coal can come in direct contact with reliable distributors of coal and to stabilize business generally. It is intended to publish a bulletin of offerings and requirements daily for distribution to members. The Bureau will not act as selling agent or purchasing agent for any member, but will attempt only to bring together parties to selling and purchasing transactions who have either in writing or verbally listed their offerings or requirements with the secretary of the Bureau.

Members desiring to purchase coal must state the quality and delivery desired, while a member offering coal for sale shall state the price, quality and to what pool it will be consigned if shipped to tidewater, and the location of the coal at the time of offering en route or at tidewater.

All offerings and requirements must be in the hands of the Secretary, in writing, by 4 p. m. for publication that afternoon, and delivery to the members the following morning. It is provided that for the present no fee is to be exacted for the service rendered until its value to members has been demonstrated. It is also provided that the Bureau will not recognize requests for listings that do not represent proposed transactions that will comply in all respects with the rules and regulations of the United States Fuel Administration. All disputes arising between parties brought together by the secretary, or arising through compliance with any rules of the Bureau, are to be referred for adjudication to the Exchange Bureau Committee, and appeals from such decision may be made to the Board of Directors whose decision shall be final.

Oklahoma City, Okla.

Coal produced in Oklahoma during the fiscal year ending June 30, 1918, amounted to 4,489,064 tons of all kinds, according to a report covering that time submitted by Edward Boyle, chief mine inspector. This is an increase of 627,367 tons over the output of a year previous. To produce this required the services of 7607 miners working an average of 189 days a man for the year. According to the report 35 men were killed in the various mines during the year.

In explaining the report, Chief Mine Inspector Boyle says: "The report shows that 7607 miners worked to produce the 4,489,064 tons of coal averaged 590 tons per man for the year ending June 30, 1918. Placing the tonnage at the average rate of $1.01 per ton would make the earning capacity of each miner $595.90, and adding to that 78c. extra for yardage and other deadwork would make the total earning capacity of each miner $1036.10. From this must be substracted the amount of explosives. The grand total of explosives used, based upon the average cost of $2 per keg for 183,561 kegs, would be $367,122. The average cost per man for explosives is $48.27. Deducting this from his earning capacity would leave a balance of $978.83. However, this does not include expense of fuse, blacksmithing, oil, blasting, paper and other incidentals."

Victoria, B. C.

Fleet Robertson, provincial mineralogist for the Province of British Columbia, has returned from Montreal, Que., Canada, where he went, under instructions, to test the cable used in the Protection shaft of

the Western Fuel Co., of Canada, the breaking of which allowed a descending cage, loaded with miners on their way to work, to fall, carrying its passengers to instant death. It is understood that he will be able to show that the break was the result of internal corrosion brought on by the action of water. That, however, is not official, but it is known definitely that Mr. Robertson carried out some careful experiments in the laboratory of McGill University, and that, as a result, he will have some interesting statements to make, not alone as to the reason for the deterioration of the steel rope of Protection shaft, but with reference to the best means of preserving cables of similar character used in mining operations from like deterioration.

Diamond drilling of coal measures situated near the mouth of the Chemainus River, Vancouver Island, is being resumed as a result of the successful defence in the court by H. W. Treat of his Provincial title to these coal lands. The soundness of the licenses he holds, it will be recalled, was contested by the Esquimalt & Nanaimo Railway Co. Mr. Treat announced that the work would proceed a few days after the court's decision. He is of the opinion that the coal measures in question are the same as were worked by the old Wellington (B. C.) mine, the area being prospected in this instance being about eight square miles, off the foreshore. The operations, it has been disclosed, are being carried on by the International Coal Co. at the head of which is Samuel Hill, of Seattle, Wash., son-in-law of the late railway magnate, James J. Hill. It is pointed out that one great advantage possessed by this property in the event of the existence of coal in commercial quantities being proved, is its accessibility. Its location on the waterfront, it is figured, will permit coal to be placed in the hands of dealers at least 50c. a ton cheaper than can be done in the cases of most of the Island mines.

PENNSYLVANIA

Anthracite

Mahanoy City—An explosion of gas at the No. 11 colliery of the Lehigh Coal and Navigation Co. on Nov. 18 cost the life of one man and injured six others, three seriously.

Scranton—In deeds filed on Nov. 19 in the office of the Recorder of Deeds of Lackawanna County, the John Gibbons Coal Co. gains title to property in the vicinity of Ripple St., near the operations of the concern. One piece of land, improved with a washery, switches and outbuildings, was bought for $18,000. The grantors reserve the right to a silt bank on the lot for a term of five years. Culm and mine refuse is also included in the piece.

Plymouth—A threat to strike on Dec. 1 if the new wage scale granted recently to the miners of the anthracite field is not antedated so as to become effective Oct. 1, has been made by members of local union No. 311, of this town. A delegation from this union is to leave for Washington to try and have the wage award made retroactive. The Plymouth men contend that the workers generally are not satisfied with the terms of the latest wage agreement.

Bituminous

Midland—The Crucible Steel Co. is perfecting arrangements for the immediate construction of a large battery of coke ovens. The Cleveland & Pittsburgh Railroad Co. is making track extensions here to take care of the increased business that will result as soon as the ovens are completed.

Pittsburgh—The Moore coal holdings of approximately 2500 acres on the Youghiogheny River, in Westmoreland County, has changed hands for about $1300 an acre, or $3,250,000, according to an announcement made recently by a party interested in the property. It is said the coal passes to the Pittsburg Coal Co., and at the time the deal was consummated several interests were anxious to buy the coal. It is the Pittsburgh vein, and comprises one of the largest single tracts on the Youghiogheny. Many efforts to purchase it have been made in the past, but heretofore all offers submitted have been declined.

Uniontown—An offer to either buy or sell is the answer of S. A. Carson and G. H. Hochheimer, majority stockholders of the Pennsylvania Fuel Co., on the application of F. E. Markell for a receivership. The terms of the offer are for the book value of the stock on Nov. 1. In case Markell declines to do either, the answer filed here sets forth the directors will discontinue the business and distribute the assets to the stockholders. Rigid regulation of the coal business by the Fuel Administration resulted in the reduction of salaries of officers, in one instance, $1000 per month, the affidavit asserts. During the coal boom Carson receved a salary of $1250 per month, and Hochheimer $1750 per month. On Jan. 1, 1918, the papers set forth, Carson's salary was reduced to $600 per month and that of Hochheimer to $750 per month.

WEST VIRGINIA

Hughey—A total of $75,000 will be expended by the Peach Creek Coal Co. upon the construction of a plant at Hughey, in Logan County, in connection with the operation of a drift mine there, work on the plant having started on Nov. 10. The company plans a capacity at the outset of 40,000 tons yearly and eventually 60,000 tons. N. E. Steele has been elected president of the new concern.

Peytona—Extensive improvements have been made by the Laurel Branch Coal Co. at its plant at Peytona on Coal River, the company having installed a new power plant and having added new mining machines to its equipment.

Williamson—Improvements have been made on an extensive scale by the Winifrede Thacker Coal Co., of which R. G. Stevens is superintendent, at its plant near here, a new 300-kw. power plant having been put in in addition to the construction of a number of miners' houses. The company has also put up a new store building.

Williamson—The capacity of the Blocton plant of the Naugatuck Coal Co. has been materially increased by the opening of a new mine in the top seam. Many new dwellings for miners and a clubhouse have been completed.

Sprigg—In order to keep pace with the increasing capacity of its plant and the large number of employees used, the P. M. C. Coal Co. at its plant here has found it necessary to erect more houses for miners and a new store building. The company is under the management of Earl McConnaughey.

Williamson—Construction work is under way at the plant near here of the Superior Thacker Coal Co. A number of dwellings for miners as well as other new buildings for the plant are being erected.

Himler—Improvements in progress at the plant here of the Himler Coal Co. include the erection of a number of new houses.

Downs—The Rachel mine of the Consumers Fuel Co. of Pittsburgh, has wrought some decided improvements under the managership of E. F. Miller. New storerooms, and an office and machine shop have been built and ninety modern dwelling houses erected. A clubhouse has been fitted up for the use of the company's employees. The mine is a shaft operation and is equipped with modern machinery throughout. Working conditions are excellent and the miners like to locate here.

ILLINOIS

Du Quoin—The Equitable Coal and Coke Co. is erecting a coal rescreener at its mine here. The work is being done by the engineering firm of Allen & Garcia, of Chicago, Ill. Construction is of steel and reinforced concrete.

Auburn—The Auburn & Alton Coal Co. made a record run at its mine on a recent Saturday when 1266 tons of coal were hoisted to the surface, after it was mined. It took 1044 pit cars to haul the coal from the mine to the elevator. This is believed to be a record for mining coal in this vicinity, and shows how hard the miners and attendants have been working to supply the coal needs of the nation. The mine has been in operation for a number of years and has always maintained a high record for efficiency. L. W. Senseney is the operator for the mine and Joseph Menzie is the mine manager.

Springfield—The production of coal in the Springfield district is now nearer normal than at any time since the influenza epidemic began. Several mines which have been shut down are now working again, and those which have had a partial force at work are now operating full time. The Jones and Adams mine, which had been working during the past few days with only 158 men, has practically its whole shift of 500 men back at work. The Woodside mine is also in full operation. Reports coming into the office of the subdistrict indicate that only about 200 miners in the Springfield subdistrict are not at work at present.

Springfield—Two former officials of the United Mine Workers, Duncan McDonald, of Springfield, and George L. Mercer, of Canton, are candidates for president of the Illinois Federation of Labor. The election is to be Tuesday, Dec. 12. Each was formerly secretary-treasurer of the Illinois miners' organization. McDonald has latterly devoted his efforts to furthering the coöperative movement.

Alton—Farmers in this vicinity are mining their own coal. Pits abandoned years ago are being operated to supply the rural demand and a number of new openings have been made where the coal vein is near the surface and a supply sufficient to keep the home fires burning on the farms is being taken out.

KENTUCKY

Stone—In addition to erecting a number of miners' houses at its plant at this place, the Sudduth Coal Co. has also put the finishing touches on a tipple at its No. 2 mine.

Toler—Considerable progress has been made on the new work at the plant of the Bailey Coal Co., the company having completed a number of new houses which constitute a part of the plant.

Pinson Fork—The Marietta Coal Co., which recently increased its capital from $25,000 to $50,000, plans development of coal properties on the Pond Creek branch of the Louisville & Nashville R. R., near Whitesburg, Ky. E. A. Gorman and Louisville interests are said to be behind developments in Perry County. However, new development work as a whole is slow just now, as labor and material are hard to secure, while conditions do not warrant any great amount of development.

ALABAMA

Sayreton—The Roberts & Schaefer Co., of Chicago, Ill., has recently completed a large new coal washer for the Republic Iron & Steel Co. at its mine here to replace the washer destroyed some months ago by fire. The washer is of the Elmore type jig.

OKLAHOMA

McAlester—The sale of the coal and asphalt deposits underlying the surface of 441,107 acres of the segregated mineral land in the Choctaw and Chickasaw Indian nations will take place here on Dec. 12. McAlester has the advantage of shipping facilities on the Missouri, Kansas & Texas and the Rock Island roads, and already is the center of a coal region with a fortnightly payroll of over $500,000.

WASHINGTON

Seattle—Alaska has begun the shipment of its vast stores of anthracite coal, according to information received here from the northern territory. The deposits in Alaska are the only ones on the west coast and for many decades have been locked in the north by legislation. With the information of the shipment of anthracite comes the news of the completion and formal opening of the Alaska Anthracite R. R., 22 miles long, running from Controller Bay to Carbon Mountain. The first trainload of anthracite, consisting of 100 tons, reached tidewater over the new railroad. Since that the mines have been shipping 300 tons a day. It is expected the output for this year will be almost 100,000 tons.

Foreign News

Vienna (via Basel, Switzerland)—M. Zerbik, minister of public works, has asked the Austrian foreign minister to address a telegram to the governments of the United States, Great Britain and France showing the extremely critical situation in Austria concerning coal and food. The public works' minister says there is no coal for the heating of houses and that the supply for cooking will not last more than a week. Mills and bakers will be compelled to close, he adds, within a few days. No further coal supplies are available to keep the railroads running, he says, and the gas and electricity services in Vienna cannot be kept going more than two or three weeks.

Ottawa, Ont.—In a bulletin issued by the Advisory Council for Scientific and Industrial Research A. S. L. Barnes, assistant engineer of the Ontario Hydro-Electric Commission, states that it is scarcely conceivable that electric energy can successfully compete with coal, oil and gas for heating purposes. Its main use will always be for mechanical power. He points out that it would need 960,000 hp. to heat the houses of Toronto alone, while the output of Niagara is only 780,000 hp. The whole possible Ontario development would be about 6,000,000 hp., which would be quite inadequate to supply the existing homes with heating alone, exclusive of all other requirements. In any event, the cost of coal would have to rise to not less than

$15.50 per ton before it would be as dear as electricity at 35c. per kw.-hr. Electric heaters as auxiliaries may prove useful in mild weather for short periods, but Mr. Barnes considers that there are scientific and economic difficulties which render impossible the idea that the water-power of Canada can be utilized on a large scale to solve the fuel problem.

Personals

Henry E. Mulligan, who for some time has been associated with S. D. Brady at Fairmont, W. Va., as engineer, has accepted the superintendency at the mines of the Abram's Creek Coal Co. at Oakmont.

George C. McIntosh, of Huntington, W. Va., has severed his connection with the United States Fuel Administration, where he held the post of publicity agent, to accept a similar position with the Solvay Collieries Co. with headquarters at Huntington.

John J. McNulty, mine foreman of the Thomas shaft of the Hillside Coal and Iron Co., transferred to No. 1 shaft of No. 9 colliery, Pennsylvania Coal Co., to take the place of **David Alexander,** who died recently. The change is a promotion for Mr. McNulty.

Orville Stump, superintendent of the Menden coal mine, owned by the Boonville Mining Co., of Boonville, Ind., was married Nov. 20 to Miss Lucia Hemenway, sister of James A. Hemenway, formerly United States Senator. Mr. and Mrs. Stump will reside in Boonville.

Harris Booker, of Monongahela City, Penn., has resigned as general superintendent of the Diamond Coal and Coke Co., of Pittsburgh, Penn., to accept a like position with the United Coal Corporation of Pittsburgh, effective Dec. 15. Mr. Booker succeeds Edward H. Coxe, whose resignation was noted in the Nov. 21 issue of Coal Age.

Obituary

John Woodmansee, superintendent of the Herminie Coal Co., of Herminie, Penn., died recently following a lingering illness. He was 56 years old and leaves a widow and three children.

Coming Meetings

Kentucky Mining Institute will hold its winter meeting Dec. 6 and 7, at Lexington, Ky. Secretary, Charles W. Strickland, Huntington, W. Va.

American Society of Mechanical Engineers will hold its annual meeting Dec. 3-6 in New York. Secretary, Calvin W. Rice, 29 West 39th Street, New York City.

War Service Committees will meet Dec. 4, 5 and 6 at the Million Dollar Pier, Atlantic City, N. J., under the auspices of the Chamber of Commerce of the United States.

Coal Mining Institute of America will hold its annual meeting Dec. 4 and 5 in Pittsburgh, Penn. Secretary H. D. Mason, 911 Chamber of Commerce Building, Pittsburgh, Penn.

Publications Received

Fusibility of Coal Ash and the Determination of the Softening Temperature. By Arns C. Fieldner, Albert E. Hall and Alexander L. Feild. Bulletin 129. Department of the Interior, Bureau of Mines. Illustrated, 146 pp., 6 x 9 inches.

Power: Its Significance and Needs. By Chester G. Gilbert and Joseph E. Pogue, of the Division of Mineral Technology, United States National Museum. Smithsonian Institution, United States National Museum. Bulletin 102, Part 5, the Mineral Industries of the United States.

Trade Catalogs

Grounding Facts. Paragon Electric Co., Chicago, Ill. Booklet. Pp. 22, 6 x 9 in., illustrated. Embodies the results of years of experience and experimentation in this very interesting field. The booklet will afford valuable information to electrical engineers.

Curtis Pneumatic Appliances. Curtis Pneumatic Machinery Co., St. Louis, Mo. Catalog No. 63. Pp. 84, 6 x 9 in., illustrated. Covers air compressors, air hoists, trolley and trolley systems, sand blasts, pneumatic and hydro-pneumatic elevators, jib and traveling cranes.

Hess-Bright Ball Bearings. Hess-Bright Manufacturing Co., Philadelphia. Pp. 108, 5½ x 9¼ in., illustrated. Bound in stiff board covers and excellently printed, the volume is in reality a treatise on the history and development of ball bearings. Typical ball-bearing applications are described and illustrated. The 26 pages in the rear of the book are devoted to general information and prices.

Industrial News

Bellaire, Ohio—The Pittsburgh-Belmont Coal Co. has increased its capital from $700,000 to $800,000.

Uhrichsville, Ohio—The Gilmore Coal Co. has been incorporated with a capital of $10,000 by Paul A. Romig, B. O'Donnell, W. R. Wilcoxen, P. A. Romig and B. B. Beltz.

Coshocton, Ohio—The Coshocton Valley Coal Co. has been chartered with a capital of $25,000 to mine and sell coal by R. H. Mills, F. M. Marshall, G. M. Marshall, Mary B. Mills and T. H. Wheeler.

St. Louis, Mo.—The Walter A. Zelnicker Supply Co. announces the appointment of Joseph Meyerson as secretary to the president. Mr. Meyerson was associated for ten years with the Southwestern Tariff Bureau. Another addition to the company's forces is A. Kottsieper, who will cover the Southwestern territory.

Columbus, Ohio—Reports show that new members of the Michigan-Ohio-Indiana Coal Association during the month of October numbered more than 20. Much interest is shown in the work of the organization, according to B. F. Nigh, the secretary. During August and September the association collected in excess of $12,000 in railroad claims for its members.

Louisville, Ky.—That conditions in the coal trade are far from satisfactory at the present time is shown in the small volume of development work being undertaken in the state, and the very few new companies being chartered. For a time a dozen or more new companies were chartered weekly, but for the past two or three weeks everyone has felt satisfied with leaving well enough alone.

Louisville, Ky.—R. C. Tway, of Louisville, was elected president; and John W. Williams, vice-president, of the Harlan County Coal Operators' Association at a meeting held in Knoxville, Tenn., on Nov. 19. This organization was formed about three years ago and numbers all of the principal Harlan operators in its membership. E. R. Clayton, district fuel administrator, has been secretary for several years.

Charleston, W. Va.—Conviction at the June term of the United States District Court here of discrimination in the distribution of coal cars, has resulted in I. K. Dye, general manager of the Coal & Coke Railway Co. being sentenced to serve six months in jail and to pay a fine of $1000. At the trial evidence was introduced tending to show that he had furnished cars to mines in which he was interested and refused them to other mines.

Norristown, Penn.—The expenses of the local emergency hospital, organized during the recent influenza epidemic, will be met by the fines of shippers of bituminous coal who charged the State Hospital for Insane here prices in excess of the Government figure. The cost of maintaining the victims of the plague was $6000, which amount has already been sent the local authorities by William Potter, Fuel Administrator for Pennsylvania, to whom the fines were paid.

Bluefield, W. Va.—The territory over which R. D. Patterson, production manager of the Tug River and Pocahontas fields, will exercise supervision, has been considerably enlarged, and in the future will embrace the Kenova, Thacker and other fields, which have heretofore been in the territory of J. W. Dawson, production manager. Action was taken on the change by the members of the Williamson Operators' Association at a meeting held at Williamson on Nov. 12.

Boston, Mass.—A demand for reduction of freight rates on coal coming into New England has been sent to Director General McAdoo of the Federal railroad administration by the Massachusetts public service commission. The commission says in its message that the present rates are clearly unjust and a grievous burden and that New England people have been trying for five months without success to obtain relief notwithstanding the promise of the director that a readjustment of rates would be made.

Charleston, W. Va.—The casualty list in the mines of the state during the month of October shows a total of 32 deaths. All but twelve of such deaths were caused by falling coal, slate or roof. Five men were killed by mine cars, three by motors and one by a mining machine. All but three of the total number of deaths occurred inside the mines. The remaining three met their deaths under or between mine cars. The greatest number of deaths were in Fayette and McDowell Counties, there being six in each.

Toledo, Ohio—There was a slight falling off in the tonnage loaded by the Hocking Valley docks during the week ending Nov. 16 as compared with previous weeks, but on the other hand there was a large increase in the tonnage loaded by the Toledo & Ohio Central railroad docks. The lake season is now practically over as only a few cargoes will leave the lower lake ports after Nov. 23. The Hocking Valley docks loaded 125,798 tons as compared with 160,491 tons the previous week, making a total of 4,920,858 for the season. The Toledo & Ohio Central docks during the same week loaded 135,000 tons, making a total of 2,224,000 tons for the season.

St. Louis, Mo.—The abstract and brief of the East St. Louis interests, intervenors in the bridge arbitrary case, in which the St. Louis Chamber of Commerce asks the abrogation of the 20c. a ton charged by the railroads for hauling coal from East St. Louis to St. Louis, was filed a few days ago with the Interstate Comerce Commission at Washington. The document was prepared by R. W. Ropiequet, attorney for the east side interests. The brief emphasizes that the differential is a long-existing relative rate adjustment based upon the natural advantage of location enjoyed by the east side because of its proximity to the coal fields.

Columbus, Ohio—Production figures for the Southern Ohio field for the month ending Nov. 2 showed a heavy decrease, due largely to the prevalence of the influenza epidemic. The figures were given out by W. D. McKinney, Federal representative for the producing district. For the week ending Oct. 12 the output was 314,000 tons as compared with a capacity of 472,000 tons. For the week ending Oct. 19 the output was 355,000 tons as compared with a capacity of 487,000 tons. For the week ending Oct. 26 the output was 318,000 tons as compared with a capacity of 474,000 tons, and for the week ending Nov. 2 the output was 315,000 tons as compared with a capacity of 471,000 tons.

Charleston, W. Va.—Urging a change in the standing zone regulations governing the shipment of coal, Kanawha district operators visited Washington this week to interview officials of the United States Fuel Administration and presented their arguments for a change. Members of the party are of the opinion that the coal from the Kanawha region should be shipped into Ohio and Indiana if there is a market for it there, as is contended by shippers here, it being pointed out that the quality of the coal is such that Ohio and Indiana consumers would like to use it if it can be obtained. It is now claimed that there is no longer any necessity for shutting West Virginia coal out of certain western markets.

St. Louis, Mo.—The St. Louis Fuel Committee has taken under advisement the application of the Beckemeyer Coal Co., of Beckemeyer, Ill., for a reclassification which would take it out of the Standard group and place it in the Mt. Olive group and enable it to sell its output in St. Louis for 25c. a ton more than at present. The application is based upon the claim that the Beckemeyer coal is of Mt. Olive quality. When arguments were made recently representatives of other companies announced that if the reclassification were allowed they would ask reclassification for their product on the ground that it is as good as the Beckemeyer output. Dealers present at the conference asked that if any reclassifying was to be done that it be deferred until spring so as not to affect the value of stocks on hand.

Columbus, Ohio—Ohio operators have been busy recently making out an entirely new set of reports to be filed with the United States Railroad Administration. The new reports show the daily capacity and also the daily output of every mine during the month of October. The daily capacity of the mines is determined by taking the total tonnage produced, dividing by the number of hours worked in producing it and multiplying the quotient by the number of hours in the recognized work day. The result is to be termed the "daily rating" of each mine and shall be the basis on which cars shall be distributed to the mine during the periods of car shortage.

Mine superintendents believe that it will be a difficult matter to increase the car supply of a mine where the production was cut to a low point during the month of October.

MARKET DEPARTMENT

Weekly Review

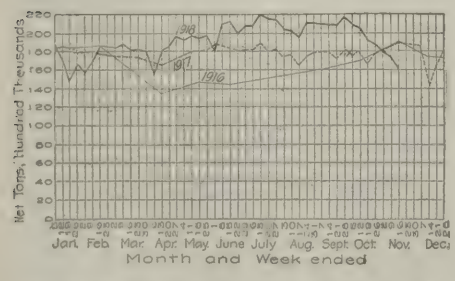
Fuel Administration Concentrating on Larger Anthracite Output — Changes in Distribution Program Necessary—Bituminous Production Falls Off Considerably — Market Not Affected—Restriction in Use of Soft Coal Removed

A NUMBER of plans looking toward an increased production of anthracite have been set afoot by the Federal Fuel Administration. Influenza and peace celebrations have interfered with the output of hard coal to such an extent as to make necessary the rearrangement of the program of distribution. Points farthest away from the mines will be cared for first, and shipments of hard coal will be withheld from sections that have already received their assigned quota.

War industries that had been granted preferential allotments of anthracite will receive this coal no longer, arrangement having been made to divert this tonnage to domestic purposes. Every possible endeavor is being made by the production division of the Fuel Administration to increase the output of hard coal while weather conditions are favorable, and to this end anthracite miners who had enlisted or been called to the colors are being mustered out of service as quickly as they signify their intention of returning to work.

During the week ended Nov. 16 the output of hard coal amounted to 1,403,000 net tons, a daily average of 234,000 net tons compared to the same period in 1917, when the production totaled 2,041,000 net tons, a daily average of 340,000 net tons. In other words, output is now being maintained at a daily rate 100,000 tons lower than in 1917. From Apr. 1 to date the total output of anthracite is 63,381,000 net tons, as against last year's production of 64,921,000 net tons for the same period.

Bituminous also registered another drop during the week ended Nov. 16 with the output of only 9,707,000 net tons. Last year's total for the same period was 1,572,000 net tons greater. Just at present this drastic slump in production has no particular significance, as the output of soft coal for the coal year to date is 40,213,000 net tons greater than the output for the same period in 1917.



If manufacturing industries adjust themselves rapidly to peace-time conditions demand will again become eager, and the present weakness in the bituminous market will disappear. All restrictions regarding the stocking and use of soft coal have been removed, the need for keeping close watch on the distribution of soft coal having passed. Low quality coals are being sold below the Government maximum here and there, though no cut in price has been reported for the fancy grades.

To sum up, the domestic sizes of anthracite are exceedingly scarce, while bituminous is plentiful, many mines having been forced to close down because of lack of orders.

WEEKLY COAL PRODUCTION

Improvement in the influenza situation in most producing fields was expected to bring about an increase in production during the week of Nov. 16, but the celebration attending the signing of the armistice offset whatever increase might have been so derived. The output during this week is estimated at 9,707,000 net tons, a decrease of 661,000 net tons, or 6.4 per cent. compared with the week of Nov. 9, and a decrease of 1,572,000 net tons, or 14 per cent. compared with the week of Nov. 16, 1917.

Whether the situation has any serious aspects depends upon the length of time required for general industrial conditions to become readjusted, the extend to which manufacturing activity will be resumed, and the rate of production that can be

maintained during the winter months. In the past two weeks, market conditions west of Pittsburgh have been increasingly important in affecting production. The decrease in seven weeks, or from the high mark of Sept. 28, has been 25 per cent., until new production is below current consumption. The low point for the present has been reached.

The average production per working day during the current week is estimated at 1,618,000 net tons, as compared with 1,965,000 net tons for the coal year to date, and 1,762,000 net tons for the same period of 1917. The total production from Apr. 1 to Nov. 16 is estimated at 389,024,000 net tons, an increase over the corresponding period of last year of 40,213,000 net tons, or 11.5 per cent.

The improvement in the anthracite production during the week of November 9 was but temporary, the output during the week ended November 16 decreasing 182,000 net tons, or 11.5 per cent. This output also fell below the corresponding week of 1917 by 636,000 net tons, or 31.2 per cent. The daily average during the week of November 16 is estimated at 234,000 net tons as compared with 333,000 net tons during the coal year of 1917, which practically represents the average daily requirements during this year. The total production from April 1 to date, for this year, is estimated at 63,581,000 net tons, a decrease of 1,340,000 net tons, or approximately 3 per cent. compared with the same period of 1917.

Reports from the carriers, for the week ended Nov. 16, show a decrease, in comparison with the week preceding, in cars loaded, from all districts, with the exception of the northeast Kentucky and southern West Virginia fields, southwest Virginia, and Tennessee and Kentucky. Considerable improvement occurred in these fields, while material decreases were noted in the central Pennsylvania field, where shipment declined approximately 4000 cars, or 14 per cent., in Ohio, where shipments declined approximately 3000 cars, or 15 per cent., and in Illinois, Indiana and western Kentucky, where shipments declined approximately 4000 cars, or 10 per cent. The current week's shipments fell far behind that of the corresponding week of last year, with the exception of southwest Virginia. For the coal year to date, however, the shipments in all districts still exceed the performance during the same period of 1917.

The lake dumpings of bituminous coal (including vessel fuel) fell considerably during the week of Nov. 16, and are estimated at 639,494 net tons. This tonnage is 21 per cent. behind the dumpings during the week of Nov. 9. For the coal year to date the lake tonnage is estimated at 28,477,112 net tons. The fuel requirements of the Northwest for bituminous coal by lake will be furnished.

Shipments of bituminous coal to New England during the week ended Saturday morning Nov. 16 estimated at 413,546 net tons, fell behind the shipments during the preceding week by 31,696 net tons, or approximately 31 per cent. Of the total stated, rail receipts through the gateways amounted to 143,470 net tons, an increase over the last week of 2.5 per cent., while tidewater shipments, amounting to 270,074 net tons, decreased 11.5 per cent. Shipments from Baltimore and Hampton Roads decreased considerably during the week, while shipments from New York and Philadelphia increased 25.8 per cent. The Fuel Administration, on Nov. 16, revised the New England budget, and the shipments for the coal year to date of 18,950,455 net tons are in excess by 2 per cent. The New England receipts by rail exceed the budget for the same period by 7.1 per cent., while tidewater shipments, as a whole are 1 per cent. behind budget.

The production of beehive coke in the United States during the week ended Nov. 16 is estimated at 553,000 net tons, or approximately 1 per cent. behind the production of the week of Nov. 9 and 70,000 net tons or 11.2 per cent. behind the production during the corresponding week of 1917. The daily average during the current week is estimated at 92,000 net tons as compared with 93,000 net tons during the week preceding and 104,000 net tons during the week of Nov. 16 of last year. Operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production of beehive coke at 275,490 net tons and the operation of their plants at 66.4 per cent. of their full time as against 69.9 per cent. during the week of Nov. 9. The same operators produced 159,250 net tons of coal.

Repairs to plants during the week ended Nov. 16 caused production of beehive coke to decrease slightly below the production of Nov. 9. The production during the current week is estimated at 571,113 net tons, and exceeds the production of the corresponding week of 1917 by 127,895 net tons, or 28.8 per cent. The plants of the country, during the week ended Nov. 16, were operated at 88.7 per cent. of their full time, as compared with 90.2 per cent. during the week of Nov. 9. The limiting factor during the week, as above stated, was repairs to plants, loss of time attributed thereto, by the operators for the country as a whole, rising from 5.7 per cent. during the

week of Nov. 9 to 7.4 per cent. A slight improvement was noted during the week in the labor situation. The states reporting a decrease in production during the week all attribute the falling off to repairs to plants, while those reporting improvement, with the exception of Indiana, give better labor conditions as the cause. In Indiana a better supply of coal brought about the improvement.

BUSINESS OPINIONS

The Iron Age—The decision of those in control of the steel industry at Washington to sweep away the whole scheme of priorities apart from those on merchant ship, railroad and navy material brings back at a stroke a substantially free market. Cancellations have come in plenty. Shell steel, wire, rails and car material represent the largest cancellations. A small but noteworthy inquiry for billets has come from Belgium, and 3500 tons of Bessemer bars are asked for the French Government. Ship plates are being sought for both China and Japan. The effects of the stoppage of Government work are not pronounced as yet, but some men are appearing every day at steel works gates seeking employment.

Bradstreet's—As the country shifts from a war to a peace basis, irregularity in movements, uncertainty about prices, and cancellations, the latter mostly of war-wanted products, are strongly outlined, these manifestations being accompanied by conservative optimism as to the future and readiness to believe that the country will respond to readjustment with a minimum of shock. Meantime, however, new buying in volume is in abeyance; the general disposition is to mark time pending the opening of clearly defined routes, and, in a word, there is considerable looking about to see what the dispensations of peace will bring forth to fill the gaps caused by the elimination of war work—an aspect that prominently stands out in the iron and steel trades.

Dry Goods Economist—In the cotton piece goods market speculators continue to sell cloths in the gray at prices 1 cent to 1½ cents per yard less than the Government price-fixing committee's quotations for the same counts. In some cases goods are being sold by speculators at prices at which they bought them some time ago. In some cases the War Industries Board has given notice to mills that when possible the relinquishing of certain contracts, or parts of contracts, for goods is desirable whenever possible, for the reason that the demobilization of troops will necessarily lessen the requirements of the Government. With mills, however, the total price recession does not amount to over 1½ cents a yard less than the prices made by the War Industries Board price-fixing committee.

Marshall Field & Co.—Current wholesale distribution of dry goods is running a little in excess of the heavy shipments of the corresponding week a year ago. Total orders from salesmen on the road were about the same, orders for immediate delivery were larger, while sales for future delivery were a little less. More customers were in the house than last week, but not so many as during the corresponding week of 1917. More or less inactivity in the retail business during the month of October due to the influenza epidemic and the unseasonable weather has been followed by improved conditions and merchants look to the future with optimism. The signing of the armistice points to an excellent holiday business. Collections continue good.

American Wool and Cotton Reporter—The ability or inability of foreign sellers to supply wool to the domestic market, and the price at which it can be supplied, taken in connection with the possible or probable conditions on cloth, is causing much speculation. There are those who feel that the raw material situation should be controlled by the Government until suitable arrangements can be made for placing the market on what might be considered a firmer basis. Buyers object to this plan, because they feel that prices will be lower, and they do not want any artificial market established.

Atlantic Seaboard

BOSTON

Manufacturing further curtailed. Trade settles down into grooves, with little inquiry. Practically no regulation locally. New England Fuel Administration ceases to order coal to loading piers. All-rail receipts materially reduced. Agitation for lower freight rates. Railroad fuel supply also falls off. Water receipts light. Problem to move accumulation at Baltimore. Less request for steamers. Future of shipping a cause for anxiety. Glaring differential between rail delivery and shipment by water. Agencies begin to wonder what steps will be taken for their relief. Possibility of through shipments from B. & O. another factor. Continual trouble with hot storage piles. Anthracite receipts show decided loss. "Free coal" increased to 100 cars daily. Complications over local allotments, prices, and two-thirds rule. Water deliveries disappointing, but improvement expected now that lake shipments have ceased. Market still absorbs broken and pea.

Bituminous—Several of the largest textile mills, as well as shoe factories and other plants for the past year engaged largely in war work, have now been notified to stop deliveries on Government contracts. One mill using 4000 tons per week and employing 5000 hands has already changed from war conditions to something like normal activity. Night work ceased a week ago, and this is typical of a large number of similar industrial units. One result is a heavy decrease of coal consumption and therefore a long extension of the time which must elapse before such interests appear in the open market.

The coal trade is marking time. Aside from a very light volume being sold in the current market, there is practically no new business that can be reported. A new contract for future delivery is a thing unheard of. Present movement is confined to those shippers who are so fortunate as to have outlets where the fuel authorities were unable to stock for months ahead during August and September when bituminous of all kinds was being poured into New England.

All embargoes and restrictions are off, so far as this territory is concerned. In effect, this was all discounted months ago, because storage and other limits had to be disregarded in order to absorb the heavy tonnage that was thrown in this direction. The bituminous department of the New England Fuel Administration is now practically disbanded, except for the adjustment of various complications that arose during the active season. All "Storrow bituminous" has now ceased moving to any of the tidewater loading piers, and it is understood that no further requisitions will be filed for "emergency" coal. Some coal of this description remains at Baltimore and at the New York piers, but doubtless all these miscellaneous tonnages will be worked off during the next few weeks.

Receipts all-rail at the five New England gateways show a greater falling off since Nov. 12 than for any similar period since last winter. From the 13th to the 18th inclusive the average daily movement of commercial bituminous was only 287 cars, a considerable reduction from the 600 cars that was the daily average only 60 days or so ago. Railroad fuel averages were only 80 cars daily, for the same period, and this also is a big reduction in movement.

Receipts by water have decreased about in the same proportion as those by rail. The different shippers have distribution in their own hands now and for that reason the ultimate disposition of cargoes seems to proceed more smoothly. Boston houses are more and more inclined to advise their principals to take what foreign business can be had, the outlook for coastwise business is so dubious for months ahead. This is reflected in current receipts which are very light at practically every forwarding point.

The only loading port where there is any considerable accumulation is Baltimore. It is only natural that in a market such as we now have there is decidedly little request for the lower grade coals from the Fairmont district. The New England Fuel Administration has several cargoes on hand awaiting disposition, but as yet no outlet has appeared. Steamers also are not in good request for coastwise coal service. At a recent meeting of Mr. Storrow's advisory committee of shippers but eight steamers were placed out of a possible twenty. This means that movement to this territory has slackened to an extent almost unexampled at this season.

One of the real problems for coal shippers appears in the very pronounced differential in favor of the all-rail routes. At points within easy access of tidewater there is now a difference in delivered cost of practically $2 per net ton, even when there is no demurrage on the water coal. This discrepancy is so glaring that the various Hampton Roads agencies are wondering what is to become of their customary business, and what measures are to be taken for their relief. The obvious first move is a reduction in coastwise rates, but not everybody is clear how this can best be managed. The recent publication of new through tariffs from B. & O. territory to eastern points has given new point to the discussion.

There is continuous difficulty on the part of large steam-users over the heating of coal in storage. Much of this arises from the great anxiety to take on as much coal as possible, but doubtless the chief cause of trouble is in the number of different grades piled together. This condition has an important bearing on the present attitude of buyers toward steam coal now seeking a market.

Anthracite—Domestic sizes received all-rail have shown a decided slump the past week. From the 13th to the 18th, inclusive, the average daily movement was but 316 cars. "Free coal," running to Mr. Storrow's order at the gateways, has been increased from 50 cars daily to 100 cars. Before the order was increased the yield through this channel was about 50 per cent., but the proportion the past week showed an improvement with respect to this emergency coal. It is understood that doubling the original order is to last until the arrears on the first order are made up.

Water deliveries continue to be very disappointing, but now that shipments to the lakes have practically ceased there is hope for improvement in the near future. Stove and chestnut are still in very short supply, and the market continues to absorb large tonnages of broken and pea.

NEW YORK

Anthracite production continues to lag and scarcity of domestic sizes becomes serious. Return of miners from war is only hope, operators believe. Police survey shows that this city lacks over three million tons. Bituminous situation in fairly good shape. Operators slow because of labor shortage and operators have many Government orders. Fairmont coals easy.

Anthracite—The return to the mines of several thousand men who are either now in the country's service or afflicted with influenza and an increase in production would be welcome news to consumers who are short of this winter's coal supply. The demand which eased up considerably because of the continued warm weather has again taken a brace, and householders are becoming urgent. That the situation is not more serious is altogether due to the urgent request of the Fuel Administration and dealers early in the year that every consumer buy his coal early.

Reports from the mining regions received here are not encouraging. They show a steady falling off, due to the inroads of the influenza epidemic, but now the authorities believe they have the situation well in hand. Despite this handicap the operators report the tonnage produced is ahead 128,942 tons for the coal year to date, as compared with the same period of last year. Efforts are to be made by the Federal authorities to increase production, and toward that end it is proposed to release about 7500 mine workers who are now in the service. The new wage scale is now in full working order.

The order of Dr. Garfield fixing maximum prices for the steam coals has not so far resulted in changes in any of the price schedules, nor has it caused any falling off in stocks. Buckwheat No. 1 is plentiful, but the supply does not cause so much trouble to shippers as it did a few weeks ago. The starting of fires in the office buildings has required more of this size. Rice and barley are nearly a drug on the market. Everybody seems to be filled up with these two sizes with no apparent demand.

The domestic sizes continue to be in heavy demand, with stove and chestnut leading. Dealers are now offering consumers egg instead of stove.

While receipts at the local docks for the week show a decrease from what they should be, the dumpings for the seven-day period ended Nov. 22 show an increase of 1344 cars over the previous week, the reports showing 5599 cars dumped as against 4255 cars.

The result of the survey of the coal situation in Greater New York made under the direction of Mayor Hylan shows a deficit of 3,577,261 tons. Much of this shortage may be accounted for by the refusal of dealers and householders to give the police the information sought on the ground that it could be obtained at the office of the local Fuel Administrator.

Current quotations, per gross ton, f.o.b., tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individual
Broken	$7.80	$8.55	Buck	$5.10	$5.90
Egg	7.70	8.45	Rice	4.65	5.10
Stove	7.95	8.70	Barley	4.15	4.30
Chestnut	8.05	8.80	Boiler	4.60	
Pea	6.55	7.30			

Quotations for domestic coals at the upper ports are generally 5c. higher on ac-

count of the difference in freight rates. Prices on buckwheat No. 1 and the smaller sizes of anthracite coal are not fixed by the Government.

Bituminous — The rescinding of the storage regulations is not expected to have any material effect on local market conditions inasmuch as most large consumers—both essential and non-essential industries—are well supplied with coal. With these stocks on hand most consumers are not inclined to do any more buying for the present, but are looking for a change in conditions with a possible change in prices. With this prospect before them they are not going to be found with a lot of high-priced coal in their bins if the market does break.

Commercial coals are in good shape. There is no great amount of free coals here, but this is entirely attributed to the decrease in production as a result of the epidemic and the lack of labor, together with the let-up in demand. Tradesmen returning from the mining fields report that conditions last week in the Clearfield regions showed signs of improvement. Production was in fairly good shape, and although labor was short, the epidemic was said to be improving. Car supply was good and operators had plenty of orders from the Fuel Administration and railroads to take the entire output.

Fairmont district coals were in better shape and plentiful. That district has not been hurt so severely as others, and the labor situation is in better shape than in almost any other mining field. Shippers had no difficulty in taking care of their orders and the demand continues to be good.

Consumption here will not be as heavy as during the past few months. Manufacturers engaged in making war necessities are dismissing their help and eliminating overtime in their factories, reducing operations to an eight-hour basis.

Receipts at this harbor are far below normal conditions but sufficient to take care of immediate requirements. Shipments of Storrow coal to New England water points are low and as in previous weeks, there are many idle bottoms in the harbor. The local dumpings for the seven-day period ended Nov. 22 were 6121 cars, as compared with 5033 cars the previous week, an increase of 1088 cars.

Just now coalmen are considering the outcome of the threatened strike of marine workers set for Dec. 1. Should the strike be called, it will affect about 60,000 men employed in and about the New York harbor and will result in all shipping being tied up.

Bunker coal is in fairly good shape here. More could be handled because of the heavy shipping, but there is no delay in coaling vessels. There is a heavy demand for the high grades from individuals, but as these mostly go into the bunkering pools there is little for outside consumption.

Current quotations, based on Government prices at the mines, net ton f.o.b., tidewater at the lower ports, are as follows:

	Mine Gross	F.o.b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite shortage of family sizes unrelieved. Production reduced by several causes. Producers and officials consider subject in closed session. Closing of training camps will release family sizes. Water tonnage to be diverted locally. Stove and nut in greatest demand. Pea grows scarcer. Steam coals unchanged. Bituminous situation still quite easy. Demand well met.

Anthracite—Conditions in the city are rapidly reaching a point where some drastic action to increase coal supplies is imperative. In times of stress we are inclined to believe that most dealers exaggerate their wants, but a recent canvass of the representative dealers shows a majority of them in desperate need of the family sizes. The stocks are lower than at any time since April, the beginning of the coal year. Shipments have not increased during the past week, and it is only due to the mild weather that there has not been serious discontent. The loss of tonnage due to the influenza epidemic was a severe blow to all the plans of the distributors. That the production is still below the anticipated figures is claimed by all operators. The peace celebration in the region, followed by several days of half-hearted work, is also responsible for a great loss of coal. There are some who claim that the recent increase in miners' wages, together with the knowledge that the war is over, has had a tendency to encourage idleness among the men. The one bright feature of the situation is that the government has arranged to release men from the army as soon as possible in order that such as are skilled in work about the mines may at once aid in increasing production.

At the office of one of the large companies it was learned that its shipments by water would be greatly reduced by the 25th inst. and that it was expected to divert a heavy tonnage into eastern Pennsylvania. This company's trade in Philadelphia has been neglected for a month, and it is believed every effort will now be made to care for it. Another company expects to be in the same position by Dec. 1, when its customers confidently expect coal. While Philadelphia dealers are "sore" and feel that this territory has been unduly neglected, they are daily growing more inclined to place the blame on the inexperience of the numerous fuel administrators rather than upon their shippers.

The increase in the retail prices due to the advance in the mines' price is causing a storm of protest, and strange to say the greatest objectors seem to be the consumers with established credit with their dealers. One of the largest suburban dealers this week expressed the determination to deliver his limited receipts to his cash customers only. He claims to be having little trouble with his C. O. D. business, but states that when coal is charged the bill is invariably returned for correction and then a lengthy and unpleasant correspondence follows. The fact that everyone signed coal cards agreeing to pay the prices in effect at time of delivery seems to have been overlooked by most of the consumers. The complaints to the fuel administration became so numerous that they were unable to handle them and this week they inserted an extensive notice in the city dailies calling the attention of the public to the facts underlying the increase in retail prices. In this it was plainly stated that the retail coal dealers' profits are not a fraction of a cent greater than they were last April, despite the increased cost of delivery.

As to the different sizes, egg remains easier than stove and chestnut, but only because there is less of it burned here and a larger proportion of it has been delivered to the consumers. Stove and chestnut are equally scarce now, with many yards without a ton of either. Pea is not in the same active demand, due to the continuance of mild weather. This is the size for which the first cold snap will bring hurry calls to every dealer from the smaller homes. Even now the stocks of it are low, with every dealer anxious for a supply before real cold weather arrives. There is not the slightest increased retail demand for buckwheat coal and the dealers do not anticipate much demand for it unless conditions become critical in the next six or eight weeks.

In the steam coals No. 1 buckwheat is somewhat easy, but the tonnage is all taken without much trouble. Rice is doing fairly well, principally due to the heavy tonnage of this size being delivered on contracts. The spot market for it has very little activity. About as much can be said for barley, while culm is out of the market.

The prices per gross ton c.o.d. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—The soft coal situation still continues easy, there being more than sufficient coal to meet every demand. While this is causing some uneasiness to shippers, yet it is generally agreed by all that it is better this way than the reverse. The bituminous producers started out to supply the industries of the country with fuel and present conditions are evidence that they have accomplished their purpose.

So far as we can learn, the government price is being maintained, although with the continuance of open weather for many more weeks there is no telling what might happen. There are plenty of rumors already that occasional shipments have been sold at a price as low as $3, but certainly no one is quoting such a price and it must have been made to move coal for special reasons. There is beginning to be quite a little solicitation for orders by some houses, both directly and by letter. This is usually on coals that in ordinary times have trouble to make the market at the full price.

BALTIMORE

An easy soft coal supply and a line of inquiries starting from the mines under new conditions. Bituminous will be available for domestic use if hard-coal scarcity continues.

Bituminous—The entire soft coal market here is easy, although for a brief time last week there was a shortage in the very best grades held for Government account, due to the fact that the Pennsylvania R. R. took over large quantities of coal that had arrived at some pools for other purposes. With a release of the industrial world by the fuel administration from all storage restrictions, a number of smaller industries are now putting away coal that is coming freely into the market. Reports with the local fuel administration show most of the large industries pretty well stocked, and some have two to four months of coal ahead. Many old connections between mines and middlemen and customers are being reëstablished or preparations made for resumption as additional Government contracts are cancelled, thus releasing preferentially held production.

The district representative during the week, on order of the national fuel administration, notified all box-car loaders that no more such coal would be applied to the accounts of state fuel administrators. This sent a flood of notices from such producers to the general trade, the offerings being at the Government price, plus 75c. Middlemen here report that they are now getting all the coal they need at the moment from regular old connections, and that inquiries they have made to mines still tied up on Government coal or Government-directed coal are answered by letters promising fuel a little later. The result is that purchasing agents here are no longer asking the fuel administration for any diversions. It may be said for the first time in months that the soft coal situation here is without snap.

Anthracite—A decided scarcity of hard coal exists here despite the rosy statements of the fuel administration nationally. The receipts in October of 45,406 tons proved a tremendous disappointment, as about twice that amount had been hoped for. Stove size is almost out of the market, many dealers offering only No. 2 (egg) or pea coal, which is unfitted for many homes. In connection with the fact that many homes here are entirely without fuel, Jere H. Wheelwright, as head of the National Coal Association, comes out with a statement that there will be no need for anyone freezing. With the war demand cut off, he points out that high-grade soft coal can be diverted to domestic use when anthracite is not to be obtained.

Lake Markets

PITTSBURGH

Greatly decreased production brings about order shutting off supplies from many consumers. Stocks will tide over. Market firm.

The Pittsburgh coal market began to show a slight softening tendency upon the signing of the armistice. Good grades of coal remained very firm, but as had been the case with certain Ohio districts for several months, the poorer grades began to show a weakening. This tendency has not proceeded, as something like a shortage appears actually to have developed, due to the sharp and continued curtailment in output caused by the influenza epidemic. Conditions became such, at any rate, that last Thursday night the Federal Fuel Administration instructed R. W. Gardiner, distributor for the Pittsburgh district, to shut off supplies of coal, with certain exceptions, from all consumers in the immediate territory bounded on the west by the Ohio River, on the south by the Pennsylvania state line, on the east, roughly, by the eastern edge of the Pittsburgh seam and on the north by the Allegheny county line. The exceptions are railroads, gas-producing plants, byproduct coking plants and retail dealers. Mr. Gardiner is given discretion as to other consumers who may be in great need of coal, such as public utility companies. In essence, this is an order requiring consumers who have stocks of coal to draw upon them until the emergency is past. The decrease in production indicated by this measure is clear when it is considered that lake shipments have ceased, although they had been running at 350,000 tons a week from the district for a long time, and at fully 300,000 tons a week late in the shipping season. It is estimated, roughly, that the influenza epidemic, reinforced by the disposition of

workmen to celebrate the cessation of hostilities, has brought the district's output down.

Prospects are that as soon as normal production conditions are restored most of the wagon-loading mines will go out of operation, as well as some others that do not produce really good coal. For standard grades of Pittsburgh coal it is expected there will be a market at the full government limits for some time, and the market is now quotable on that basis: Slack, $2.10; mine-run, $2.35; screened, $2.60 per net ton at mine, Pittsburgh district.

Many of the foreign-born workmen have determined to go to their native lands, although fewer will go than now express the intention. One coke operator reports a census taken of his workmen as follows: Twenty-five per cent. stated they would remain at work; 25 per cent. intended to make brief journeys abroad; 50 per cent. stated they were going back to stay.

The market remains quotable firm at the set limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over ¾-in., $7.30; clean screenings, over ½-in., $5.50, per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Nov. 16 at 259,930 tons, a decrease of 19,720 tons, and raw coal shipped at 185,240 tons, a decrease of 8597 tons. The heaviest coke production since the first of the year was 353,470 tons, in the week ended July 13, the average in September being a trifle over 340,000 tons a week.

TORONTO

Little anthracite coming forward. Dealers refusing new orders. Prices advanced. Market overstocked with bituminous and dealers trying to unload.

Very little anthracite is being received, owing to the large shipments which are being forwarded to the upper lakes before the close of navigation. Most of the dealers are again refusing new orders and endeavoring to overtake delayed deliveries. Consumers who were reported as being entirely destitute of fuel have all been supplied with small quantities, and owing to the unusual mildness of the weather, the shortage has not been so severely felt. The market is at present overstocked with bituminous, which is not much in demand, and some dealers are shading the government prices in order to effect sales. The price of anthracite has advanced following the increased cost at the mines. Quotations for best grades per short ton are as follows: Retail anthracite egg, stove, nut and grate, $12; pea, $11; buckwheat, $9; bituminous steam, $9.25; slack, $8.25; domestic lump, $11; cannel, $13; wholesale f. o. b. cars at destination, three-quarter lump, $6.50 to $7; slack, $5.50 to $5.82.

BUFFALO

Bituminous in good supply. Jobbers becoming more active. Some unsold coal on track. Miners getting back to work. Anthracite demanded.

Bituminous—The supply increases and the demand does not, so a surplus is in sight that may become large before long. The producer and jobber fear it and are trying to avoid it. Producers are again saying that they will shut down before they will allow prices to go below the profit line. Jobbers, of course, are anxious for enough surplus to give them business, but to maintain merely a working surplus of that sort is by no means an easy matter.

This condition of the trade means that the jobbers are going back into something of their old activity. They do not get any great amount to do yet because the consumers are holding off. The idea is that prices will decline, and as the consumers have more coal on hand than they have had in a long time it is not to be expected that the demand will run very high right away. The actual consumption is going to be large, but with the weekly production of late running well above 2,000,000 tons a week over last year a surplus can hardly be avoided.

There is talk of prices running below the regulation figures, but it is not yet reported that any really good coal has been offered at a cut, and the situation is hardly such as to warrant it right away. But for the big slowing up of mining on the outbreak of the influenza the surplus would have been large now. Then there comes a further surplus from the shutting off of the shipments to the lakes, which alone is enough to create an over supply. So the future supply is seen to be heavy in spite of all influences to the contrary.

Anthracite—The supply does not increase much, but on the whole the feeling is easier, for many people are saying that the supply will increase soon, much in the way bituminous has done. The fuel authorities still say that the allotment will be filled according to plan, and that when the people stop demanding more coal than they need it will be easy to keep ahead of the actual needs.

There is much disposition to complain of the advance in price, which brings the retail cost of chestnut to $10.50 per net ton to the curb, with 50c. more for putting in, a price that would be granted without much of a murmur if it could be made to appear warranted by any new conditions arising.

The shipments by lake continue large and will go on for a week or so longer, after which they will soon drop off. The amount for the week was 156,200 net tons, of which 79,700 tons cleared for Duluth and Superior, 17,400 tons for Fort William, 17,000 tons for Sheboygan, 16,000 tons for Milwaukee, 15,500 tons for Chicago, 6000 tons for Green Bay, 2800 tons for Hancock, 1000 tons for Depere and 800 tons for St. Ignace. This is the heaviest weekly amount this season.

CLEVELAND

Standard No. 8 coal is just able to hold its own in this market, with the result that No. 6 and stripping coal have sagged as much as $1. The tendency is all toward weakness, many operators believing the bottom will be touched between now and Jan. 1. Contract cancellation, especially by retail dealers, has assumed proportions. Production has receded, due to recurrence of influenza.

Bituminous—Decided weakness among the lower grades, which is reported to be making breaches in the better grades, is apparent on every side. Demand has narrowed until it now is just about flush with the production of Standard No. 8 coal. Consequently, concessions for other grades are sought and obtained. Coshocton slack—a No. 6 coal—has been offered at $2.40, or 25c. below the Government maximum. Top prices on bituminous from stripping operations in eastern and southern Ohio have been shaded as much as $1 in tonnage. Several big operators foresee the weakness spreading to the standard grades and are prepared to make cuts. Federal Fuel Administration officials here and many big operators declare flatly that so far no shading has been required for standard No. 8 coal, but they will not go on record as to how long this condition can continue. Operators assert there is no cause for pessimism now, with coal selling at the highest prices on record, but there is no escaping the facts that every indication discernible is one of weakness.

Readjustment of industries in the lower lake regions is well under way. Labor already has suffered a deep cut in wages through elimination of Sunday and overtime work. The much-talked-of reconstruction business so far has not developed, primarily because work will not be undertaken so long as prices, on the average, are twice as high as normal. Cessation of munitions making has thrown as high as 6000 workmen out of 7000 in one lower lake plant out of employment. Efforts of Washington to maintain commodity prices or wages by artificial means are doomed to failure, it is believed.

Industrials, operators point out, on the whole have large stocks which they will seek to work off. Thus, they will be out of the market for the present. But by the time peace requirements do come out in volume the industrials again will become coal buyers. This is the logic behind the claims of some operators that the low point in the coal market should be reached between now and Jan. 1, with a gradual pick-up coming with the new year.

Were it not for decreased production at the mines, bituminous plainly would be a glut on the market. Stocking restrictions have been entirely wiped out. The lightless-night ban has been modified and is effective now only two, instead of four, nights a week here. Three carloads of mine-run, offered at public sale by the clerk of the municipal court to satisfy a judgment, brought only $1.20 a ton. The lake trade has slowed up to the point where it is a small factor. Cancellations of contracts by retail dealers on account of no market have become numerous. Retail dealers stand together, apparently, in the belief that reduction of prices will not stimulate business, for retail prices have not been cut in the face of a dropping off of fully 50 per cent. of retail business. Influenza has returned, in spots, to the No. 8 district, and coupled with the opening of the hunting season and the general letting down caused by the signing of the armistice, production has suffered greatly. Operators, however, welcome this state of affairs just now. Car supply, too, has fallen, but this occasions no concern.

Shipments in the week ended Nov. 7 by operators who are members of the Pittsburgh Vein Operators' Association of Ohio totaled 4475 cars, compared with 8069 cars in the week ended Oct. 31 and 4882 cars in the week ended Oct. 21. Car supply reported by these same operators in the week ended Nov. 9 averaged 21.54 per cent. short, as against an average shortage of 26.27 per cent. the first week preceding and 30.47 the second.

Anthracite—Belief that more anthracite and Pocahontas would come in, with the demand at tidewater lessened, has been dispelled, and retail dealers believe receipts will become no heavier until after Jan. 1. The 1918 schedule will be continued, they understand, which means that the movement into Cleveland will hover around the 25 to 30-car a week point.

Lake Trade—The movement of bituminous to Lake Erie docks for the Northwest has fallen to the lowest point of the season to date, but the 2,388,875 tons required to round out the 28,000,000-ton allotment for the Northwest will be floated by the end of the month beyond doubt. Requests for use of equipment at both lower and upper lake docks after Nov. 23, the official closing of the lake coal season, have been few. Anthracite, undoubtedly, will be floated so long as the carriers are operated. The loading of bituminous at lower lake docks in the first half of November is estimated at 1,650,000 tons by the Coal and Ore Exchange, of Cleveland.

DETROIT

Diminished activity in the domestic and steam plant trade in bituminous is ascribed to an over-supply in the hands of buyers. Anthracite stocks are low.

Bituminous—Reserves in the hands of consumers of steam coal and in the yards of retail dealers have produced an inactive market for bituminous in Detroit. Jobbers say they meet with little success in the attempt to arouse interest in new commitments, even when the coal offered is of a quality superior to that of the stock which has recently been available.

In following the advice of the fuel administration to stock up early and take any coal obtainable, the users of steam coal and the retailers have been induced to load up rather heavily with the coal sent into the local market from Indiana and Illinois. This stock is described by jobbers as of inferior quality and is said to be causing annoyance to the industrial plants attempting to use it, as well as to the retailers, who are endeavoring to distribute it among reluctant household consumers.

The domestic demand is blunted by the weather conditions, which have not yet taken on sufficient suggestion of winter frost to stimulate buying by householders. Quite a number of the domestic consumers are also reported to be holding back in the hope of being able later to stock up with anthracite. Asserting stocks now on hand would be exhausted in a week of real winter temperature, W. K. Prudden, Michigan fuel administrator, is preparing to open two coal yards in Detroit, with the intention of storing there shipments of bituminous, which local consignees refuse to accept.

Anthracite—Demand for anthracite from domestic consumers continues strong. Applications from consumers unable to obtain supplies from dealers are being received at the rate of about 40 daily in the offices of the fuel administration, though more than 65,000 such orders were booked early in September. Of the latter, it is said practically all have been provided with a maximum of two tons, while a further distribution is planned, in case the coal is forthcoming. Receipts during the present month are falling short of the shipments in October.

Lake Trade—Practically all coal for the head of the lakes had been loaded before midnight, Nov. 23, though a few shippers who had fallen behind are sending forward additional cargoes this week, where boats are available. The demands of the grain trade for ship storage capacity have left few freighters to be had for moving coal.

COLUMBUS

Weakness in mine-run and screenings still continues. There is a good demand for domestic sizes although domestic trade is quiet because of continued warm weather. The lake trade is practically over. The tone of the market is not as good as formerly.

The principal feature of the coal trade in Ohio is the continued weakness in steam sizes. An over-production of mine-run in every field is reported and markets are flooded. This is especially true of many small mines in the Hocking Valley field, which have been opened under the stimulus of war business. Screens were not obtainable and mine-run was the only grade marketed. Another reason for the larger amount on the market is the fact that

steam users have heavier stocks of fuel in reserve than ever before. It is believed that reserve stocks average about two months and possibly more. Steam consumers have stopped buying as they are desirous of using their surplus stocks. Railroads are not taking as large a tonnage as formerly as freight movement has decreased. Michigan has been supplied by Indiana and Illinois and that section will not be in the market for some time.

Domestic trade still shows strength despite the unfavorable weather conditions. Dealers' stocks are pretty large, but there is still a good demand for prepared sizes. West Virginia grades are especially sought after. Dealers will not buy any more mine-run as they have their bins clogged. It is believed that the rural sections are the best prospects for business as farmers have been too busy to haul their fuel. City consumers have about 75 per cent. of their supply, while rural people have but 35 to 40 per cent. Dealers in the smaller towns are as a result the best customers. Retail prices are still firm at former levels.

Lake trade is now about over as only a few cargoes will move after Nov. 23. The lake season as a whole was successful and all Northwest requisitions were filled. There will be no shortage of fuel in that section. Vessel movement was much more efficient than ever and less time was lost in loading and unloading. Ohio and West Virginia furnished a large part of the coal shipped to the upper lake regions.

Production has fallen to about 50 per cent. of normal, mostly because of the influenza and peace celebration. Then the opening of the hunting season was another cause for loss of tonnage. Some few mines have been closed because of lack of orders. It is believed that eastern Ohio is producing a larger amount than any other section.

CINCINNATI

Mild weather and lack of industrial buying have produced a dull market, so that small shipments are ample to meet demand.

The effect on manufacturing of the sudden, if not unexpected, coming of peace, has been marked, in this section, especially, where so many large industrial units have been extensively engaged in the production of commodities for the use of the Government and the Allied powers for war purposes. In a good many cases these factories have already been notified that a greatly diminished activity for Government purposes will be immediately put in effect, and in other instances instructions to cease operations on contracts have been received.

A striking local instance of the manner in which industrial war work is affected is the cessation of work on the enormous air nitrates plant near Cincinnati, which was to use electric current from the local station of the Union Gas and Electric Co. This plant will not be completed, at least for Government use, and the current, and hence the coal to produce the current, will not be required.

With little need as yet for coal for heating purposes, and with the industrial market for steam fuel in the condition indicated, the entire market is extremely quiet; and as far as the steam market is concerned, it is somewhat difficult to say just when conditions will return to normal.

In many lines, particularly in machinery, it is not expected that there will be any period of actual dullness, the present caution being purely for the purpose of awaiting developments. In the mining sections some trouble from influenza is still reported, tending to reduce production, and transportation conditions are also suffering from the same handicap; but shipments are adequate, in view of the reduced demand.

LOUISVILLE

General market draggy on all lines, both domestic and steam being quiet. Lake region shipments over, and Southeastern coal now moving to retailers of Kentucky and South.

Mild weather is not helping things much in Kentucky just now, and the retailer, jobber and producer are all in the same boat—short of business, and doing everything possible to secure a market for coal. It is claimed that about 80 per cent. of the big domestic demand has been supplied for the winter, and that only cold weather will make the remaining percentage buy.

Industrial consumers are using up coal stocks on hand, feeling that the market may go lower, and that they will have no difficulty in securing coal whenever they require it, with the result that they are playing safe on uncertain business.

Receivers are becoming finicky concerning grades at the present time, and are turning down shipments on the claim that the grades are not as represented, this resulting in some coal paying demurrage on track.

For the first time in months a good supply of eastern and southeastern lump coal is coming on the market. However, many retailers are well stocked on Hazard and western Kentucky lump and are accepting little additional coal, having all they want for the present. However, retailers out in the state that were not able to secure western Kentucky, Hazard or eastern Kentucky, which latter was moving to the lakes for months, are now just beginning to get some stocks laid up in advance of cold weather.

A shipment of nine barges of Pittsburgh coal which came down the Ohio River a few days ago represented the first received in eight months. Eight barges went to New Albany, Ind., one barge of lump being delivered at Louisville. The E. T. Slider Co. and the River Coal Supply Co. had the entire shipment, which consisted of six barges of lump, two of slack and one of mine-run.

At the present time there isn't much demand for eastern Kentucky coal, West Virginia or Pittsburgh on the local market, as there is not a ready demand, and the price is so strong that it takes too much money to stock a yard on such grades. Retailers in many instances have a month to six weeks supply on hand and are not unloading any additional coal until they reduce stocks.

Continual reports are being heard concerning producers and jobbers cutting prices 15c. a ton and more in order to get business. Some mines with no more than a day or two of business ahead of them are willing to accept almost any price to get business, and the value of a good sales manager is again demonstrating itself.

BIRMINGHAM

Railroads short of coal. Domestic demand strong. Operating conditions show a little improvement.

While the local coal market is not specially strong for the steam grades, the requirements of the trade are now greater than the supply coming from the mines, due to the fact that the railroads have been taking the maximum obtainable under their contracts, during the past few weeks, thus interfering with regular shipments to other classes of consumers, who are now beginning to run low on stocks. Railroads securing fuel in this zone are reported to be very short and are exerting efforts to expedite heavier movements of coal from the mines. An increase in the tonnage of bunker coal required from this district is expected about the first of the year or sooner, as more shipping is expected to be diverted to the Gulf ports in the near future.

The domestic trade is without change, there still existing a strong demand, which is much in excess of the supply available, and some steam coal is being prepared and diverted to domestic channels.

Coal production appears to be picking up a little this week with the return of more miners to their tasks. Operating conditions were very unsatisfactory during the past week, the peace celebration completely disconcerting the regular routine, and mine workers were slow to return to their labors, and the output, which had been so seriously crippled by the influenza epidemic for several weeks, showed little improvement. The production for the week ending Nov. 9 was 348,306 net tons.

Coke

CONNELLSVILLE

Further decrease in coke production and raw coal shipments. Market quite firm. Labor migration in prospect.

Nothing could have done more to support the market from the shock of the cessation of hostilities than the continuance of declining production of coke. Week by week the influenza epidemic has reduced output, while week before last the celebration of the termination of hostilities made further inroads on production, and a payday at the close of the week paved the way for a continuance of the celebration last week. Consumption of coke is at the former rate, there being no disposition on the part of blast furnaces to slow down or blow out, even for repairs that in several cases will have to be made within no great length of time.

Generally speaking the hope of coke producers is that the market will stay up to the government limit of $6, while the expressed expectation of consumers is that there will soon be a drop, and one of no small proportions. The Fuel Administration's maximum price does not seem to have a definite time limit, and as the administration's control is permitted to the declaration of peace, the control will only be taken off by definite action of the Fuel Administration, and this is not likely to occur. The blast furnace and steel interests have shown such coöperative spirit in the past that they have some expectations of adhering to government maximum price for pig iron and steel as long as they are maintained, but the coke producers are hardly in the same category; and it is possible that if shading of government limits began it would soon run to important proportions.

Until production is restored to something like normal there can be no question as to prices. Consumers have always felt that the $6 coke price was rather high, even as compared with $2.35 for Pittsburgh district coal, which they do not consider a low price by any means. The coke trade is short of labor, or the influenza epidemic would not have had such a remarkable effect in decreasing production, and the present outlook is for decreased supply in some respects.

Buffalo—The demand is good, but the supply is now sufficient to meet it, all the furnaces here getting what they want, most of it coming from their own byproduct ovens. Fuel coke still sells pretty well, though it partakes something of the weakness of bituminous coal. It is now quite out of the question to find sale for the coke culm piles which were opened a few weeks ago and thrown on the market. Iron ore receipts are now dropping off materially, as the season is practically at an end. The amount reported by lake during the week was 197,100 gross tons, scarcely more than half the former movement.

Middle Western

GENERAL REVIEW

Middle West market continues weak. Poor grade coal selling below Government maximum. Guiding hand needed to keep market from falling to pieces.

The coal market in the Middle West continues to be very weak. There is one noticeable fact, however, and that is that the high-grade coals, from both Illinois and Indiana, are selling at the full Government prices, and for the present at least, not showing any signs of weakening. The poorer grade coals, however, have been offered very freely of late at considerable discounts from the Government price, and in a great many cases even this discount has been of slight inducement to the average purchasing agent.

The state of Michigan has all the coal on hand that it can comfortably assimilate, and not only are Illinois and Indiana coals allowed to go to all points in the Southern Peninsula, but coal from Ohio, West Virginia and the two eastern districts of Kentucky can now move to Michigan, and are being readily purchased, with the natural result that the poorer grade coals from Illinois and Indiana are being practically shut out.

The State of Illinois has been unable to take care of the coal produced within its own borders, nor has Iowa or Wisconsin been able to absorb its surplus. Indiana coal today is consumed practically within its own borders. This is because to date eastern coal is not allowed to move to points in Indiana, and Illinois coal cannot compete, in most cases, with Indiana coal, when the low freight rate of the Indiana product is brought into consideration.

There are a great many opposite views relative to the immediate future of the coal industry. It is freely said that unless the Government steps in and controls the basic industries, by establishing a minimum price, as well as a maximum price, that the coal industry will suffer a tremendous loss. This is because the producing mines must be kept running, and in order to keep their labor organizations together, the operators, nine times out of ten, are willing to make very substantial reductions in order to move their product and keep their organization intact.

The optimists of the coal industry believe that conditions will soon change, and that the renewed activity along manufacturing lines will be able to absorb the coal produced by this country. One example quoted was a large factory, which, before the war, was engaged in the manufacture of veneer work, used in building. When this country entered the war, the manufacture of building material was curtailed, but most of the manufacturers received Government contracts to keep them running for the time being. The firm we have in mind at once engaged in the manufacture of propellers for aeroplanes. In the meantime, all the surplus veneer stock they had in their storerooms was sold, and they accumulated a very large number of orders to be filled after the war. A few days after the armistice was signed, these people had their propeller contract canceled, and their plant is now down, but within a very short time will reopen, and all their activities will be concentrated on producing veneer work.

The Middle West has been enjoying a long period of mild weather, and as a result but little coal has been consumed. The market will be helped by the coming of cold weather. Furthermore, a number of larger industries which purchased coal during the season and stored it are now consuming it beneath their boilers as fast as possible, and it is fair to assume that they will be in the market again within six weeks.

What the situation lacks at this time, more than anything else, is a strong guiding hand to keep timorous operators from losing their heads altogether, and cutting each other's prices down to a point where the cost of production will not be covered.

CHICAGO

Little activity is shown in market conditions. Cold weather expected to help dealers. High-grade coal bringing full Government prices.

There is little activity in the coal market of this city. The large consumers are out of the market and will be out of the market for some time to come, as they are doing all possible toward reducing their substantial storage piles. There is practically no demand for coal in Chicago. The only people who are purchasing coal at this time are doing so to take advantage of reduction in price made them by some producer or jobber.

The domestic situation continues to be extremely dull on account of the mild weather. It may be confidently looked forward to that as soon as a cold snap comes there will be a revival of activities in the domestic trade. Practically the only domestic coals that are holding up to the full Government price are the high-grade and specially prepared products from the southern part of Illinois and from the Clinton district of Indiana.

MILWAUKEE

Shortage in anthracite making it unpleasant for dealers. Illinois coal being pressed upon the market. Lake receipts slowing up as the season of navigation nears an end.

The main feature of the coal situation at Milwaukee at present is a shortage of anthracite. Colder weather finds many consumers waiting for supplies ordered months ago, and naturally the disappointed ones are appealing to other sources for relief. State Fuel Administrator Fitzgerald calls attention to the fact that no dealer has been accorded more than 50 per cent. of the amount sold in 1916, and that while there are cases where dealers have not as yet drawn their full allotment, it does not signify that they are in position to take on any new orders. He advises everybody to stick to their regular sources of supply.

There are huge piles of bituminous coal on the docks and consumers of this character of coal have little to fear. In addition, Illinois operators are unusually active in pressing their products on the market. There has been no cutting of prices of Illinois coal as yet, but this may follow. This condition is directly the opposite to that which prevailed a year ago, when anything having the semblance of coal was eagerly absorbed. Illinois coal is being freely advertised at prices ranging from $7 to $7.75 per ton, with an extra charge of 50c. for delivery into bins. Nearly all coal docks are experiencing fires in soft coal piles, but thus far no serious loss has resulted therefrom.

Lake receipts are slowing up to a noticeable extent. Many of the coal-carrying craft are now taking down grain to Buffalo to be held in the vessel until spring. This reduces the tonnage available for coal for the remainder of the season. Receipts during the month of November, thus far, aggregate 87,077 tons of hard coal and 162,568 tons of bituminous. This brings the cargo receipts by lake since the opening of navigation up to 647,046 tons of hard and 3,313,697 tons of soft coal. Anthracite is still coming by rail in fairly liberal quantities.

ST. LOUIS

Slightly colder weather has not improved market, which is continually slipping. Steam and domestic demand light. Prospects poor. Mines idle, with equipment plentiful and transportation good.

The local situation is a depressing one. With slightly colder weather on the 21st, and the first sign of snow of the season on the 22d, the market is in a demoralized condition as regards Standard coal. Standard 2-in. lump went as low as $1.75 and screenings down to $1.40, with 6-in. lump going as low as $2. Even at these prices the mines were obliged to shut down on account of no business. Some mines have only worked one day in the six, and even then had a hard time placing tonnage.

Steam business has dropped off on account of the large plants using up their storage coal, and the munition plants using up what they had in sight, not knowing how much longer they would be allowed to continue. Offsetting this there should be some business from the brick, tile and cement plants and other industries that have been running on short time as nonessentials, but if there is anything like this in sight it has not materialized to any extent as yet.

Car supply in the Standard field is more than any mine can begin to take care of and transportation is good. Labor is plentiful, and the only thing that worries the operator at this time is finding a market for his coal.

In the Mt. Olive district an effort has been made on the part of the operators to keep out of the sea of despondency, and they have pretty well succeeded on account of their railroad business. There has, however, been a good tonnage of domestic coal moving to the north from this district and the prices are holding up remarkably well.

Referring to railroad coal brings out the fact that many mines in the Standard field that had railroad contracts are idle, and while there is no evidence on hand to prove that the railroads are buying on the open market at lower prices, yet their failure to take the contract coal has greatly depressed the market. The mines that are getting railroad business are the only ones in the field that are working anywhere near regular time.

In the Carterville and Duquoin field a large tonnage is moving on railroad orders, but there is a surplus at the present time in all of these fields of lump, egg and nut coal, and some mines are finding it hard to move their product, having unbilled coal at the mines daily. This is in both Williamson and Franklin County. The car supply here is plentiful and there seems to be nothing to worry the operator here, other than a place to put his product.

The Government maximum price here, with the exceptions above noted, is:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.75	$2.55@2.75	$2.40@2.70
3x6-in. egg	2.55@2.75	2.55@2.75	2.40@2.70
2x3-in. nut	2.55@2.75	2.55@2.75	2.40@2.70
Washed:			
No. 1	3.05@3.20	3.05@3.20	.....
No. 2	3.05@3.20	3.05@3.20	.....
No. 3	3.05@3.20	3.05@3.20	.....
Mine Run	2.35@2.50	2.35@2.50	2.20@2.30
Screenings	2.17@2.32	2.17@1.32	1.50@1.60

Special preparation on Carterville is 10 cents extra.
Williamson & Franklin Co. rate is $1.10.
Other fields 95 cents.

The prices in the Carterville and Duquoin fields have not been cut to any extent. In a few isolated cases the operators have given certain jobbing interests 15c. off of the $2.55 Government price, so that the top of the market in this district is $2.55.

There are some operators with special permits of 10c. a ton for extra preparation, but there is an effort being made to have this done away with very shortly.

There is still a heavy percentage of the men missing from the mines on account of the influenza, but it is growing smaller gradually.

The cut mine prices have not, however, affected the retail prices in St. Louis as yet. The Standard price of $5.45 has been cut by one or two dealers to $5 and the Carterville price of $6.20 delivered has been cut to $6, but this is not general nor is it likely to be.

Assistant Fuel Administrator John C. Hall has conducted several hearings the past week or two in connection with dirty coal shipped by southern Illinois coal companies to points in the State of Missouri. Mr. Hall is also director of enforcements, and an active campaign is going to be made from now on against all violations of dirty coal, etc.

General Statistics

NORFOLK & WESTERN

Below is given a statement of the coal tonnage from mines on the Norfolk & Western R. R. and from other railroads, for the month of September, 1918:

From	Net Tons
Pocahontas field	1,373,366
Tug River district	283,232
Thacker district	244,785
Kenova district	101,536
Clinch Valley district	160,423
Other N. & W. fields	13,214
Total N. & W. fields	2,176,556
Williamson & Pond Creek R. R.	196,433
Tug River & Kentucky R. R.	63,665
All other railroads	72,505
Grand total	2,509,159

OCTOBER ANTHRACITE SHIPMENTS

Shipments of anthracite for the month of October, as furnished to the Anthracite Bureau of Information, amounted to 6,286,366 tons as compared with 7,110,950 tons for October last year, and 6,234,395 tons for the month of September this year, showing a decrease as compared with October of last year of 824,584 tons, and an increase as compared with September of this year of 51,971 tons.

The average daily shipments in October of this year were 232,828 tons against 263,368 tons for the corresponding month last year, a decrease of 30,540 tons in the daily production for the month. This decrease can be attributed to the recent epidemic of influenza which passed over the region and resulted not only in the loss of a great deal of time, but a loss of life in a great many instances. When everything is considered the output for the month of October is commendable and a credit to the anthracite industry.

The shipments by companies were as follows:

	October 1918	October 1917	Coal Year, 1918	Coal Year, 1917
P. & W. R. R.	1,115,340	1,425,265	9,111,369	8,988,139
L. V. R. R.	1,216,391	1,314,896	8,910,548	8,685,842
C. R. R. of N. J.	601,180	604,295	4,175,925	4,141,140
D. L. & W. R. R.	982,966	1,153,661	7,054,540	7,368,299
D. & H. Co.	739,495	813,429	5,514,544	5,284,571
Penna. R. R.	393,885	430,662	3,260,441	3,300,307

COAL AGE

Volume 14 New York, December 5, 1918 Number 23

The Invincibles

Written expressly for *Coal Age*

By RUFUS T. STROHM

NOT all the brave are the men who died
On the hallowed soil of France
To stem the flood and to turn the tide
Of the gray-clad Hun's advance;
For here at home there are hosts of men
Of a loyal, sturdy mold,
Whose splendid deeds neither tongue nor pen
In a fitting way has told.

THEY are the men who remained to fight
By the working face and rib,
And cleaved through the solid anthracite
With the aid of fuse and squib;
For when the war in its lengthened course
Brought an increase of demands,
They bent their backs and they put new force
In the labor of their hands.

THEY heard no sound and they had no sight
Of the battle's raging hell,
And yet they shared in the grilling fight,
And they did their duty well;
But though the race of the boche is run
And the nations talk of peace,
The task of the miner is not done,
For the country's needs increase.

THE winter comes in the waning year
With an icy, numbing breath,
And millions quake with a growing fear
Of disease and cold and death;
But while the threat of impending woes
Makes their bravest spirits quail,
They lift their hands and their eyes to those
Who have not been known to fail.

□

YE men of brawn and of sympathy,
Who have heard their urgent cries—

YE miners, what will your answer be
To the pleading in their eyes?

Underground Mining with Electric Shovels

By E. J. WITTHOFF
Cleveland, Ohio.

SYNOPSIS — *The ordinary well known steam shovel, reduced in size and driven by electrical energy, is growing in favor with mining men. This type of machine has been used for several years, particularly in iron mining. Cost records show a decided saving by their use.*

ELECTRIC shovels are becoming increasingly desirable and essential in underground mining. For years many of them have been used in underground iron, coal, zinc, limestone and salt mines. Their performance has definitely established them as highly productive, economical factors in this class of excavation.

The chart, Fig. 1, shows the power demand of one of these shovels in a New York iron mine. It is equipped with a 20-hp. motor and the record is of loading five consecutive cars of ore. For car No. 1 the average demand was 16.04 hp.; for car No. 2, 20.75 hp.; for car No. 3, 16.25 hp.; for car No. 4, 17 hp.; for car No. 5, 14.25 hp. This shows an average of 16.86 hp. for the total five cars.

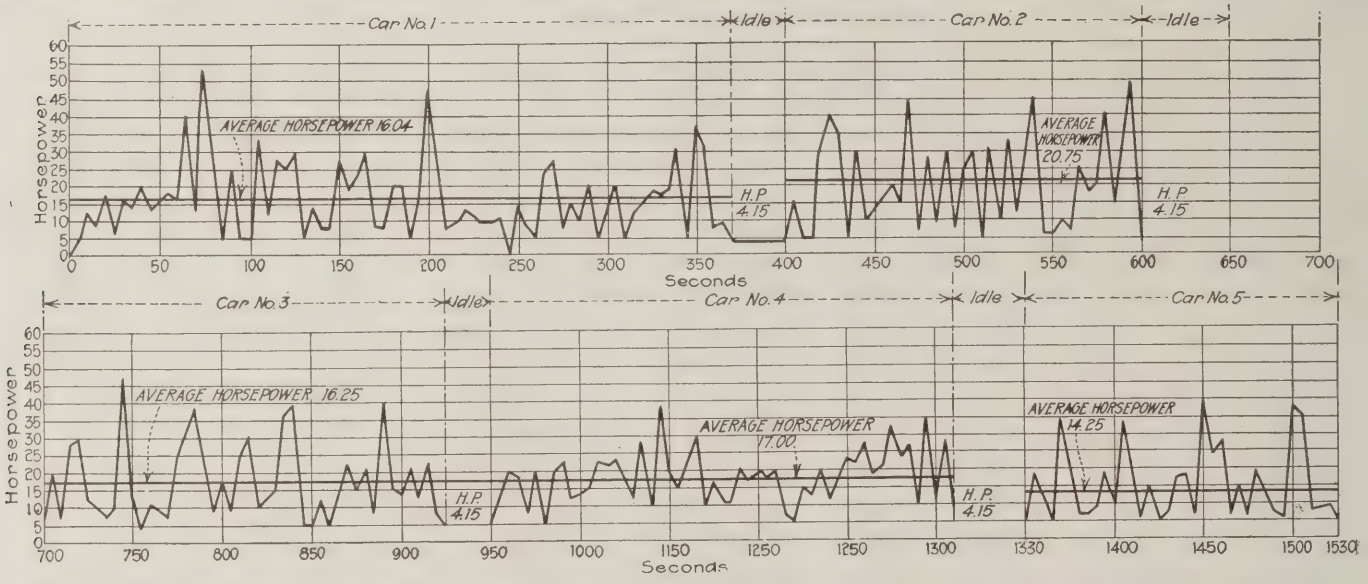

FIG. 1. DIAGRAM SHOWING POWER CONSUMPTION OF MINING SHOVEL LOADING FIVE CONSECUTIVE CARS OF IRON ORE

Below is a detailed statement of the complete operating costs of this shovel for the last four months of 1917 and the first five months of 1918:

Month, 1917	Cars	Tons	Labor	Supp.	Power	Total Cost	Cost per Ton
Sept.	1,084	3,794	$384	$224.65	$9.98	$618.63	$0.163
Oct.	1,713	5,995	432	21.30	15.70	469.00	.079
Nov.	378	1,042	204	122.86	3.24	330.10	.317
Dec.	1,148	2,296	384	11.54	10.10	405.64	.177
1918							
Jan.	1,064	2,128	400	56.05	9.70	465.75	.219
Feb.	1,396	3,290	524	131.27	13.20	668.47	.203
Mar.	1,756	5,268	800	241.80	17.00	1,058.80	.201
Apr.	2,095	6,285	832	177.41	18.90	1,028.31	.164
May	2,390	7,170	864	238.29	24.50	1,126.79	.157
Total	13,024	37,268	$4,824	$1,225.17	$122.32	$6,171.49	
Avg.	1,447	4,141	536	136.13	13.59	685.72	$0.166

These costs cover all the expense involved in actually loading the ore and tramming it about 300 ft. to the main haulageway. They include, also, the expense of moving the shovel to different levels and locations. The ore was loaded into 3-ton gable bottom cars.

Under identical conditions and per-ton loading cost by hand-labor was 30c. and by shovel 16.6c. The saving per ton effected by the shovel was 13.4c. or $5000 in nine months, which is equivalent to a 7 per cent. return on a $100,000 investment.

A northwestern iron company has used a similar electric shovel for about 4½ years. The ore was 25 per cent. fine, 75 per cent. lumps, the largest pieces being 2 x 2 ft. x 18 in. This shovel loads 150 to 220 tons daily.

The following table gives the tonnage and the average cost per ton, for each fiscal year, ending June 30, from 1914 to May 1, 1918:

Year	Electric Shovel Tonnage	Electric Shovel Cost	Hand Operation Tonnage	Hand Operation Cost	Saving
1914	20,820	$0.268	102,438	$0.466	$0.20
1915	24,497	.253	34,222	.324	.07
1916	32,261	.304	84,485	.318	.01
1917	31,530	.344	77,653	.391	.05
To May 1, 1918	26,439	.408	59,646	.510	.10

Fig. 2 shows a Thew electric shovel, built by the Thew Automatic Shovel Co., of Lorain, Ohio, mining iron ore underground.

In a western zinc mine a mining shovel loaded 125 cars in 5¾ hours at a cost of less than 9c. per ton, including tramming. This represented a reduction in cost of handling material and hauling it to the shaft for hoisting from 16c. and 18c. per ton by hand to 9c. by the shovel, a direct saving of 45 to 50 per cent. Today five of these shovels are working in this mine.

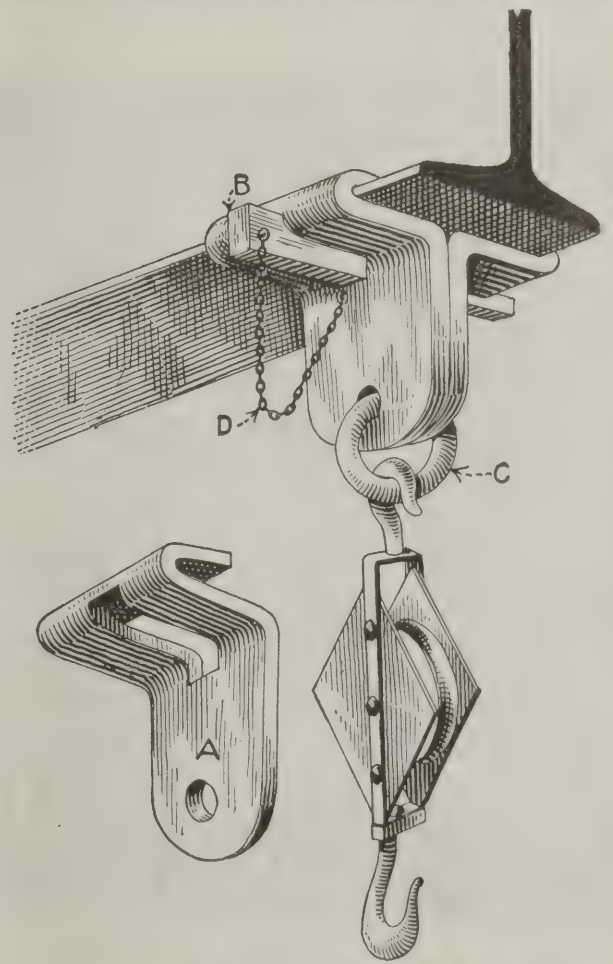
The construction of an underground mining shovel is novel, not in the sense of being new and untried, but in being a somewhat radical variation from the standard full-circle swing type of steam shovel. This mining shovel is really an abridgement, a "pocket edition" of larger shovels, but with a pronounced difference in construction and working features to adapt it to advantageous and profitable use under the conditions pe-

culiar to underground operation. It possesses all the rugged strength and dependable digging ability of the bigger shovels in concentrated form. Its compactness does not, however, complicate its control, for it is easily operated by one man. A mine laborer of average intelligence can soon learn to handle it and produce good results.

Compacting the construction of the shovel—minimizing its over-all dimensions—was the basic step in its adaptation to underground mining. Besides the restricted operating rooms, narrow entries and passageways had to be considered, as well as the shaft through which the shovel is taken into the mine. The shovel is so built that it can be quickly dismantled for passing through these restricted areas and speedily erected for succeeding operations. A remarkable instance of the "knocking-down" ability of these mining shovels is that a recent installation could be disassembled for taking through a 3 ft. 6 in. by 3 ft. 8 in. shaft.

FIG. 2. SHOVEL USED IN UNDERGROUND MINING

Loading cars with facility and speed means keeping them moving. An excavator that requires the exact spotting of cars for receiving their load handicaps production seriously. Conditions often make it inadvisable, impossible, or too expensive to place track for locating cars in a certain, definite position. An underground mining shovel, rotating through a complete circle, has the advantage of being able to work in any direction; to load cars easily and quickly, either at the side of or behind the machine. The result is increased production and reduced overhead expense.



Experience has proved that electricity is the ideal power for these underground mining shovels. It is economical, safe and easily handled. Electricity need be used only while actually digging. Current can be switched on or off instantly. Electric power eliminates the dangers of explosions in coal mines caused by gases coming into contact with an open fire.

The motor is of the single, constant-speed type, with friction controls. All electrical equipment and connections are simple and may be readily understood by the operator. Hoisting, crowding, swinging and propelling movements are all controlled direct from this motor, in this manner minimizing physical effort on the part of the operator and enabling him to easily speed up tonnage delivery.

Every underground mining operation involving considerable output and affording sufficient working clearances can advantageously use one of these shovels. Their real worth is well summarized in the words of a mine superintendent: "The principal advantage is more production with fewer men, at less expense."

Quickly Detachable Clamp

A quickly removable clamp which can be used anywhere about the mine where I-beams are used is shown in the accompanying illustration. The clamp is made of two sections of machine steel, *A*, each being slotted to receive the taper key *B*. In operation the sections *A* are clamped tight against the lower part of the beam by means of the wedge. The hanging ring is welded after passing through the lower holes of the sections. The holes should be large enough to allow free motion of the ring in order to permit setting and removing the hangers from the beam. For the sake of keeping all parts together, the key may be fastened to one of the sections by means of a small metal chain, such as is shown at *D* in the illustration.

DETAILS OF EASILY DETACHABLE CLAMP

Loading Out Coal with Electric Shovels

By W. B. BRENNAN
Cheyenne, Wyo.

SYNOPSIS — *Electric shovels have been used for several months in a coal bed 30 ft. thick that pitches 18 deg. Their use has proved financially profitable; and since the shovel is full revolving, delivery to pit car may be made at any of at least three points. Much of the transportation difficulty often encountered with so-called mechanical loaders is thus obviated.*

IN ORDER that a clear idea may be gained of the conditions under which shovel operation underground is conducted, it will be necessary to describe briefly the mining property and the coal bed. In mine No. 4 at Hanna, Wyo., where electric shovels are used in loading, the coal bed pitches 18 deg. and is nearly 30 ft. thick. This mine is reached by a slope driven down the pitch, off which entries are turned on the strike. At 1000-ft. intervals along these entries panel planes or slopes are driven parallel with the main slope. From these panel planes rooms are driven, and it is in these that the shovels are employed. These rooms are approximately 28 ft. wide and 18 to 20 ft. high.

It will readily be perceived that a room of rectangular cross-section driven on the strike in such a coal bed will have the upper corner on one side near the roof and the lower corner on the other near the floor. The bottoms are kept practically level and the entire room lies within the confines of the coal measure. Some coal is left in the roof as the shale above the coal bed will not stand.

When it was first attempted to operate with these shovels, it was the endeavor to cut, shoot down and load out daily. This did not prove satisfactory, however, as enough coal could not be secured from one undercut to keep the shovel operating throughout an entire shift. To overcome this, rooms were driven along the bottom with a height of 6 ft. into the face for a distance of 300, 400 and even up to 600 ft. When a room of this kind was made, the shovel moved in and 12 to 14 ft. of top was shot down. This gave the necessary coal to keep the shovel working.

This has proved fairly satisfactory, and at the present time two shovels are working continuously; a third is about ready to be installed, and plans are on foot for a fourth one to be put in operation within the next six or seven months. These shovels are of the electrically driven full-revolving type. One is a 16-ton Type 00 Thew machine, while the other is a 32-ton Type 1 of the same make. In either case three men are required with a shovel, one man operating the machine, the other two part of the time working on the coal pile and part of the time trimming the mine cars or wagons as they

SHOWING ELECTRIC SHOVEL IN SUCCESSFUL USE UNDERGROUND

are loaded, so as to get the maximum capacity on each without delay. The larger shovel loads from 175 to 225 tons daily and the smaller one from 140 to 180 tons.

It has always been my opinion that mechanical loading underground was quite as much a haulage problem as a loading one, if not even more so. Of the various types of mechanical loaders heretofore developed, practically all employ a conveyor which either discharges at a fixed point where it is necessary to place the pit cars or requires complicated machinery to handle the coal to various destinations. With a shovel which revolves it has been found that three different points exist where cars may be loaded without difficulty. This makes it possible to keep the shovel in operation continuously, there being no delay caused by waiting for cars to be spotted.

If a machine as expensive and complicated as a coal loader is to be made a commercial success, it is necessary to keep it in operation continuously during the entire working period of the mine. This is what it has been endeavored to accomplish with these shovels. This goal has been attained with considerable uniformity, there being not many more delays with these machines than occur with any machinery underground.

The first shovel has now been in operation since January, 1916, and the second since July, 1917. They are working daily and load about the average tonnage mentioned above. The most serious delay thus far encountered arises when it is necessary to move a machine from one loading place to another. This of course takes considerable time with a machine the weight of one of these shovels. Working places are, however, being so arranged that the various moves occur only four or five times per year per shovel.

The rate for loaders working after mining machines in the southern Wyoming field is 49c. per ton. These men lay their own tracks and timber rooms where necessary. Coal is undercut and shot by the company. It has been found in the use of these shovels that the actual cost of loading coal into the mine cars is only about 15c. per ton, but other expenses are involved, such as changing tracks, setting timber where necessary and a certain amount of switching which has to be done by the company men in connection with the shovels, such as is normally done by the loaders where they work under contract. Thus the cost of shovel loading averages 28 to 32c. per ton, which includes all labor, repairs on shovels, power and any other charges that can possibly be chargeable against mechanical loading. The effort has always been to make the charges against this method of loading as complete as possible.

In hauling to and from the shovel to the panel slope, mule haulage has in some cases been employed; but, where the rooms are long enough to justify it, locomotive haulage has been installed. This has proved quite satisfactory. The shovels are equipped with wide tractor wheels which travel on the bottom, and as the shovel moves forward the tracks are laid behind it.

As to the future of coal-loading machinery, it is my opinion that some type of loader built along the general lines of a shovel that will pick up the coal and be able to dispose of it in various places will be the successful mechanical loader of the future in mines giving 7 ft. or more of headroom. A loader of this type could be made to travel on mine tracks and should not weigh much more than an arcwall or straight-face mining machine. A machine of this type with a properly designed boom and bucket could work in 7 ft. coal beds and load cars of a fair size to a reasonable capacity.

My experience with machinery in general underground is that it must be as simple and rugged as possible, since the class of labor obtainable is such that delicate and complicated machinery will not be found serviceable. Experience in this mine would indicate that the electric shovel meets the conditions admirably.

Testing a New Breathing Apparatus

By John Lyons
Carterville, Ill.

In order to test the new Gibbs standard two-hour breathing apparatus a number of employees of the Madison Coal Corporation on Oct. 4 last journeyed by automobile to the Illinois state mine rescue station at Benton, Ill. The party was composed of William Turton, district superintendent; John Lyons, rescue foreman; Herschel Harriss, assistant mine foreman; John Lauder, face boss, and Fred Schoonover, safety inspector.

These men were well received by James Weir, superintendent in charge, who clearly described the different

METHOD OF ADJUSTING BREATHING APPARATUS

types of safety lamps and rescue apparatus kept at the station. The new Gibbs apparatus was explained and the machine thoroughly tested for leakages, careful note being made of the amount of oxygen contained in the cylinder at the start of the test and the amount used in a given time.

John Lyons was the first to wear the machine, the gage at this time showing 135 atmospheres. He performed work in the smoke gallery, such as pulling the 50-lb. weight, sawing props, crawling through the 17 x 19-in. tunnel, carrying a 130-lb. dummy single-handed round the gallery and then carrying the body end of a stretcher bearing a 160-lb. man with another man carrying the foot end. Lyons worked as fast as possible, not stopping at any time to rest. Unfortunately no record was kept of the actual work done. At the end of 30 min. the apparatus was taken off. The gage

now read 75 atmospheres, showing that during the work-period of 30 min. 60 atmospheres of oxygen had been used, or almost one-half the capacity of the cylinder when fully charged. This amount equals 116 liters, or an average of 3.86 liters per minute for the 30 minutes.

Without recharging, Mr. Harriss at this point put on the apparatus, with the gage showing 75 atmospheres. A correct record was kept of the work performed by him, which was as follows: Trips around gallery (100 ft. per trip), 29; pulled 50-lb. weight 3 ft. high 90 times; pushed pit car a distance of 60 ft. 16 times; carried 130-lb. dummy single-handed 360 ft.; sawed props 4 in. in diameter with dull saw once; went through 17 x 19-in. tunnel once. The total time occupied during this work was 30 min., and the total amount of oxygen used was 40 atmospheres, or 77 liters, being an average of 2.56 liters per minute.

Mr. Schoonover then put on the apparatus without recharging, the gage reading 35 atmospheres. He walked round the gallery for 10 min. and was then forced out because he had no oxygen in the cylinder. The gage readings showed that he had used 35 atmospheres in 10 min., equal to 67 liters, or at the rate of 6.7 liters per minute. Undoubtedly there must have been something wrong with the gage, causing it to register more than the cylinders actually contained. No person under any condition, no matter how hard the work, is capable of using up so much oxygen. Experts consider that 3 liters per minute would be the maximum quantity used in hard work.

Special attention was given to the behavior of the automatic feed valve on the apparatus, which is said by the makers to allow sufficient oxygen to the wearer no matter at what speed he may be working and to reduce the quantity passing when the wearer ceases work or rests; also the temperature of the inhaled air from the breathing bag. The three wearers all agreed on the following opinions:

That at no time did they have to slacken their speed because the automatic valve was not delivering sufficient oxygen, enough being supplied at all times.

While the purifier got so hot that it could not be touched with bare hands, the temperature of the inspired air did not seem to rise perceptibly throughout the trials.

At no time did the breathing bag get so full as to make it uncomfortable to breathe against. This is brought about by the automatic release valve, which releases the air in the breathing bag when it reaches a certain pressure. However, it was thought that owing to this valve releasing easily it might have been the cause of using up such an excessive amount of oxygen during the period of 70 min. in which the apparatus was worn.

The center of weight of the apparatus is too high on the back, causing the person wearing it to have to lean forward in order to maintain his balance. A glance at the side view photograph accompanying this article illustrates this clearly.

It was also thought that the casing that covers the main part of the apparatus could be made a little lower. The present type comes too much in contact with the wearer's head when he bends down for such work as pulling the weight.

There should be some different arrangement for holding the gage when this is not being read. The wire clips now in use allow the gage to jump out when the wearer of the apparatus is using a saw or pulling the weight machine.

The foregoing trials were made with men well trained in the use and care of mine-rescue breathing apparatus. They are members of the rescue brigades which are maintained by the Madison Coal Corporation at its Carterville mines. These brigades have helped the state teams at explosions occurring in the southern Illinois coal field during the last four years, including the recent disaster at Royalton.

Coal Mine Proves a Sand Pit

Wheeler & Mason, coal operators of Columbus, Ohio, while opening a stripping operation on a tract of approximately 275 acres near New Lexington, Ohio, discovered a valuable deposit of molding sand. This is now being developed by the Perry Coal and Sand Co., chartered to produce and market the sand. Since Jan. 1 of this year the concern has marketed over 700 cars of the sand, which has proved highly successful in use.

Late in 1917 Mr. Wheeler started to clear the ground

REMOVING MOLDING SAND BY STEAM SHOVEL

by steam shovel preparatory to mining the 5-ft. bed of No. 6 coal which is on the property. After throwing a considerable amount of the sand aside, it was discovered that the overburden was probably more valuable than the coal deposit. Accordingly, an $80,000 sand plant was erected and operations started as rapidly as possible. The deposit is 18 ft. thick and covers approximately 100 acres of the tract.

Under the sand is a 5-ft. stratum of shale which will be left for the present. Later on it is expected to remove the shale and market the coal beneath it.

Some of the most important equipment units requiring immediate attention following an explosion at a mine are as follows: Ventilating appliances, hoisting appliances, signaling appliances, brattice boards and canvas, props and ties, tools, nails and spikes, and miners' safety and portable electric lamps. An experienced man who has some qualifications as a leader should be detailed to look after each of the units mentioned and should be furnished such volunteer assistance as will constitute an efficient working force. Each of these foremen should then immediately proceed to perform the duties assigned him and organize his force into shifts of six or eight hours.—*Rescue and Recovery Operations in Mines.*

Elimination of Power Losses*

By GRAHAM BRIGHT
East Pittsburgh, Penn.

SYNOPSIS—*A shortage of power for industrial purposes has developed within the past few months. Various measures may be taken to alleviate this condition, some of which, such as changing the starting hour of the work day, might be considered as drastic. Electric operation of mines offers many possibilities of saving over either steam or compressed-air operation.*

THE shortage of power supply in most of the central stations of the country, and the greater value of fuel, makes the economical use of power not only increasingly important but an actual necessity. The real economic use of power means not only the elimination of power losses, but the proper distribution of power in order to improve the load factor and permit of more customers being served or more apparatus being used with a limited amount of power-producing equipment. The large increase in industrial power consumption due to war conditions has loaded most power plants beyond their capacity, and a number of schemes have been devised to assist the central stations to take care of the abnormal conditions.

The first natural solution is to install additional capacity in the isolated plant or central station. There are, however, several objections to this. In the first place the financial condition of most mining companies and central stations is such that even if they could obtain the consent of the Government, and could raise sufficient money to purchase additional equipment to make the necessary changes in power plant and transmission lines, the high cost of equipment, material and labor at the present time would scarcely justify the investment, especially when the conditions after the war are considered, at which time the industrial loads will probably decrease and the fixed charges on the new equipment will be much higher than under normal conditions.

A study of the load curve of a large central station will indicate to a considerable degree how the system can be relieved and how additional loads can be taken care of. The average central station load curve shows that the load from midnight until 6 a. m. is from 25 to 50 per cent. of the full load during the day. At 6 a. m the load rises rapidly, reaching a maximum between 8 and 9 a. m. At noon the load suddenly drops off about half but rises rapidly again at 1 p. m. to about the same value as before noon. Between 3 and 4 o'clock in the afternoon the load starts to drop off, especially if there is much running load. If there is considerable railway and lighting load, there will be a rise again from 5 to 7 o'clock in the evening, after which the load will gradually decrease until midnight.

When a fair percentage of the load is mining, considerable assistance can be given the power station by shifting as much load as possible from the day to the night turn. Many mines are doing most of their pumping and cutting at night, which assists the load factor by decreasing the day load and increasing the night load.

*Paper for presentation before the Coal Mining Institute of America, Pittsburgh, Penn., Dec. 5, 1918.

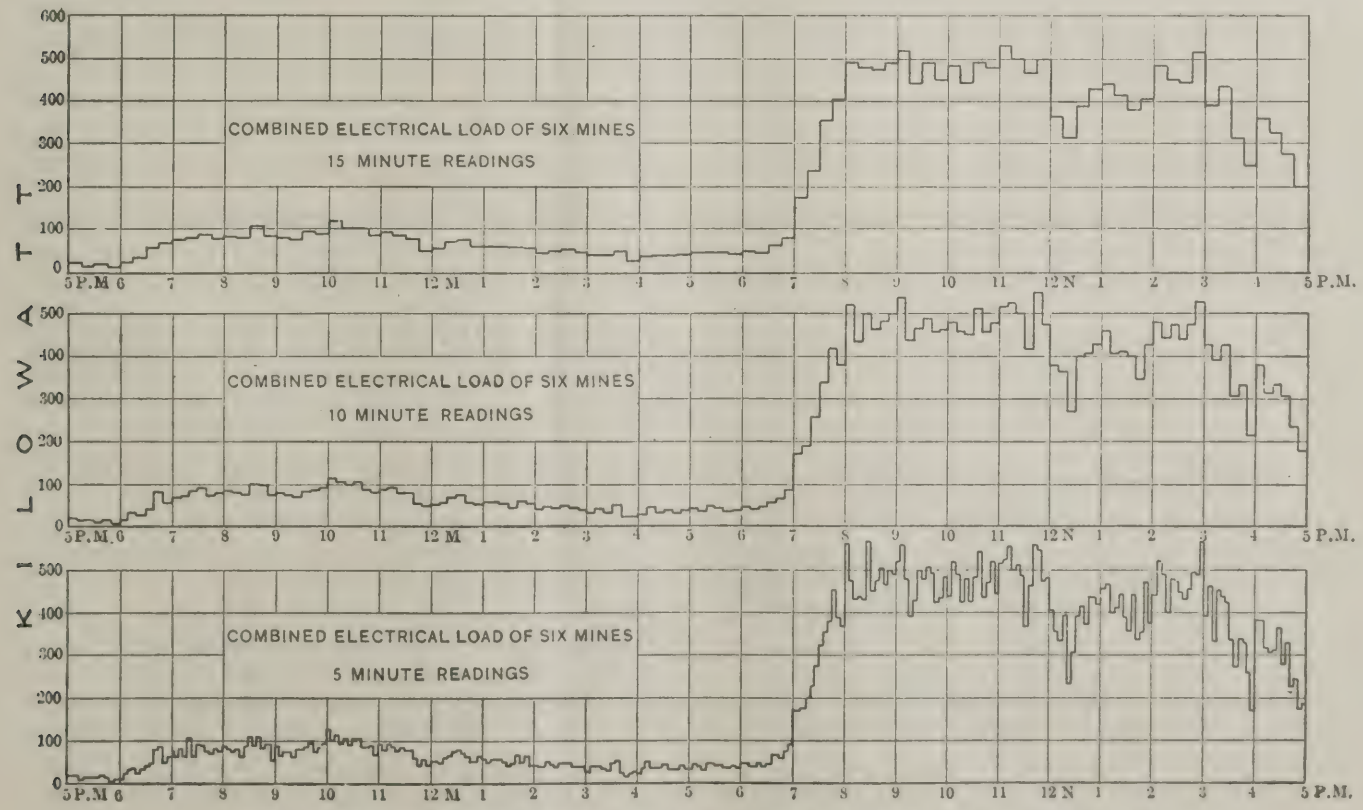


FIG. 1. READINGS SHOW LARGE VARIATION BETWEEN DAY AND NIGHT LOAD

This incidentally permits of more customers being served with a given amount of power station equipment. Some additional help can be given by changing the starting time and lunch hour of the day shift at some of the mines. In a few cases the rather drastic method of shutting off each customer in rotation for a short period two or three times a day has been necessary where the capacity is insufficient to take care of all the customers at the same time.

The curves shown in Fig. 1 were plotted from tests made simultaneously at six mines located in the same vicinity, the tests being made to determine the general shape of the load curve, the diversity of six mines compared to one, and the relative values of the 5-, 10- and 15-minute integrated peak loads, for a full day's run of 24 hours. These curves indicate the large variation between the day and night load and show that the load factor and capacity required could be considerably improved if some of the day load could be shifted to the time between 5 o'clock p. m. and 7 o'clock a. m. Incidentally the sum of the maximum peak loads of the individual mines shown in Fig. 1 was 50 per cent. greater than the combined peak.

There are two ways of helping out the power station irrespective of whether it is a central station or isolated plant. The first is to eliminate power losses wherever possible, and the second is to so schedule the use of power as to improve the load factor so as to require less capacity of power equipment.

Power Losses in Isolated Plants

In regard to the elimination of power losses, the mine with an isolated plant will be first considered. It is not always fair to compare the practice at a mine plant with the average central station because of the fact that the mine plant is generally located in an undesirable section far away from industrial centers, where living conditions are such that it is difficult to obtain and keep high-class labor. The average single mine cannot afford to employ experts continuously to keep the various parts of its power system in the best of condition. This places it at a disadvantage when compared to a mine using central station power.

Beginning with the boiler plant, considerable saving can be effected by employing an expert from time to time to go over the entire equipment carefully, and not only make recommendations regarding improvements and repairs, but carefully instruct the firemen regarding best methods of firing, cleaning fires, adjusting drafts, taking care of the ashes, etc. It is considered the best practice in a modern boiler plant to work the boilers at not less than 100 per cent. overload to give the best all-round efficiency. It is doubtful if there are many mine boiler plants where it is possible to work the boilers above rated load. This means that more boilers are in use than necessary and the individual boilers cannot be taken out of service long enough to give them the thorough cleaning and inspection they should have.

The water question is a most serious one in many mine boiler plants, and the proper treatment of boiler water requires an expert.

Some of the defects which should be watched for closely and where considerable saving can be effected if corrected, are as follows: Improper firing; defective settings; irregular inspection and cleaning; insufficient draft; no lagging on steam pipes and insufficient lagging on boilers (this is especially true in the South, where boilers are often mounted in the open without any sort of building protection whatever); leaky blow-off; leaky traps.

The engine room or other location using steam engines is a fertile field for the efficiency engineer. The fan engine is about the only engine around a mine on which the load is steady enough to permit of economical operation. Indicator cards often show that the engines are much underloaded and it is impossible to obtain high economy. The advantage of such an installation is that it will operate over long periods with little or no trouble. Considerable saving could be effected, however, by installing the proper size of engine or adopting motor drive.

In the engine room proper, where engines are used to drive generators, considerable saving in power can frequently be effected. The valve settings should be regularly checked by taking indicator cards, and no engine should be operated unless absolutely necessary. The load on a small or medium sized mine generator is extremely variable, so that high economy cannot be obtained. Fig. 2 illustrates a portion of a typical day

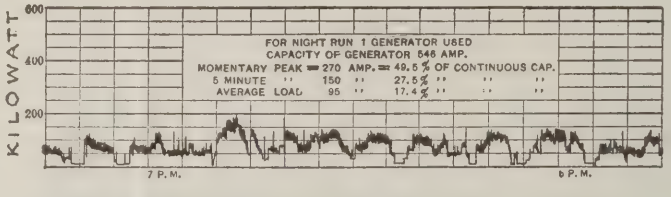

FIG. 2. DAY LOAD ON 1902-AMP. MINE PLANT

load on a plant having a capacity of about 1000 tons per day, and shows the wide variations in load that take place in a short period of time. The capacity of the generating equipment to meet a load of the character shown in Fig. 2 is based on the maximum peak instead of the average, and if the engine driving the generator is based on the average load it will be found that it will not have sufficient power to drive the generator at the maximum load.

The situation is often aggravated by the steam pressure being somewhat lower than the pressure for which the engine was designed. The result is as shown in Fig. 2, where it was found necessary to operate two generators during the day, having a combined capacity of 1092 amp., when, if sufficient driving power were available, one generator of less than half the total capacity would have been ample. Considerable saving in power could therefore be effected with the proper installation of engines and generators, but where possible a much greater saving could be effected by the installation of motor generator sets or rotary converters, using central station power.

Fig. 3 shows a typical section of the night load on the same plant. This curve shows that the generator and engine are operated over long periods at far below their normal capacity. This curve shows the advantage that would be obtained if a portion of the day load could be shifted to the night turn, permitting the generator to operate at nearer its full load capacity, thereby causing more efficient operation.

The real saving in power about the ordinary mine plant is shown by the adoption of central station current and the elimination entirely of all steam operation. If we compare the operation of the plant, portions of whose load curve are shown in Figs. 2 and 3, with one using central station power, we will find that the latter plant would require but a single 100-kw. rotary converter and, besides a considerable saving in power, the cost of operation would be much less.

In haulage a great amount of power is frequently wasted. A few mines use compressed-air locomotives, and this type of machine is inherently inefficient. One has simply to visit the compressor plant of a mine using compressed-air locomotives to realize that considerably more power is required than would be the case where an electric haulage system is installed.

I have in mind a particular installation near Pittsburgh where compressed-air locomotives were formerly used for the main haulage. The distance was about 10,000 ft., and in bringing a loaded trip from the inside it was necessary to stop six times to charge the air tanks. Since a large portion of the power required under such conditions is due to acceleration, one can readily imagine the extremely low efficiency of such a performance. The compressed-air locomotives on the main haulage have recently been replaced by electric machines, and a great saving both in power and labor has been effected.

Large Transmission Losses Costly

With an electric system of haulage, pumping, cutting and ventilation, there are often many opportunities to effect power saving. This can be accomplished by scheduling to an extent the use of power to improve the load factor and to improve the line and return circuit conditions so as to eliminate a large part of the transmission losses. Large transmission losses not only needlessly waste power but greatly shorten the life of the equipment, cause numerous delays and increase the cost of repairs.

These losses, when excessive, have a deleterious effect on the entire output of the mine. Much time is lost due to slow-speed operation, and the men will be idle a considerable portion of the time waiting for cars and because of delays arising from breakdowns and burnouts.

The electrical equipment is frequently blamed for troubles and delays where the real cause is in the transmission system. The remedy for low voltage does not always consist of the installation of additional copper. Frequently it will be found that the low voltage condition is due to poor splices in the overhead system or poor bonding in the return circuit. It is needless to say that all connections and splices in the overhead system should be carefully soldered and the bonding system frequently tested. Cross bonds should be installed about every 200 ft. and all switches, frogs and cross-overs should be carefully bonded around. Every mine should either have a bond-testing instrument or be able to borrow one periodically.

Where different trolley and feed wires run to adjacent localities in the mine, they should be frequently connected together in such a manner that the various circuits will help each other out. This will often be of great assistance, since the maximum load seldom occurs in more than one circuit at the same time. The returns in power saving, decrease in delays, burnouts and repairs, together with the actual increase in output, will more than pay for the extra time and expense involved in improving the voltage conditions in the transmission system.

It is frequently found that considerable saving in power and capacity can be obtained by changing some of the maximum grades in a mine so as to take less power and permit the locomotive to handle greater trips.

Comparing the haulage system of mines to a street railway system, one seldom sees a broken-down car on the latter or hears of long delays due to defective equipment. This is largely due to two things—regular and systematic inspection and the use of spare equipment. The street railway companies and the large steel mills have found that rigid and regular inspection pays for itself many times over in the elimination of costly delays and breakdowns in service.

The actual cost of repairing a breakdown is frequently but a small proportion of the total cost, which arises chiefly from vexatious delays and loss of revenue and output. The proper inspection and upkeep of the equipment will therefore tend to keep the entire operation

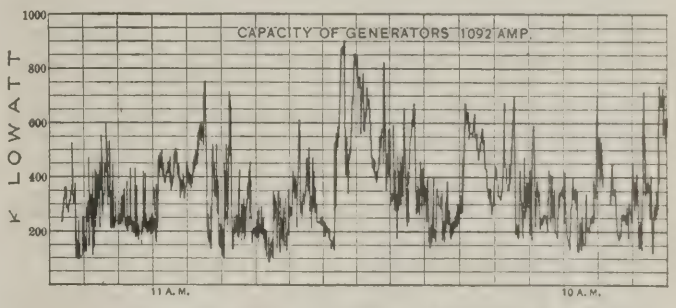

FIG. 3. EVENING LOAD ON 600-AMP. MINE PLANT

in logical working order and will eliminate a loss which is inevitable when part of a system breaks down and the remainder must operate, requiring normal power at a time when the output is greatly reduced.

Compressed air is sometimes used to operate steam pumps, in which case the efficiency is extremely low. The installation of a motor-driven pump would show a large saving in power. Considerable loss takes place in long air lines installed in mines. Air leaks do not have the property of "taking-up" like steam leaks, and are sometimes difficult to locate and repair. A leak in an electric circuit is soon detected and easily repaired, so that the loss in such a circuit will as a rule be much less than in a compressed-air line. It is not an uncommon sight to see a large steam-driven compressor operating over a long period when the only load on the air system consists of two or three small pumps, each of which could be operated by a 5-hp. electric motor. The load on the compressor in this case would probably be from 100 to 150 hp., largely due to the friction loss of the machine and the air leaks in the system.

The electric pump is without doubt the most efficient method of removing water from a mine. Where it is possible to do so, a further saving can be effected by arranging to do a large part of the pumping at night, in order to improve the load factor.

The ventilating system does not lend itself to changes which will improve the load factor. The fan must ob-

viously operate at full speed during the day when there is the greatest demand for other power. There are many cases, however, where the speed of the fan at night can be reduced, thereby causing a large saving in power. Where a speed reduction of 2:1 is required, this can be readily obtained with the electric motor and the efficiency at one-half speed will not be far below the full load efficiency. This of course is not the case where a steam engine is used to drive the fan. The addition of booster fans will often accomplish certain results with much less expenditure of power than if the same results are obtained by speeding up the main fan.

As long as a piece of apparatus about a mine operates and causes no delay, its performance in regard to efficiency is seldom inquired into. A steam hoist is notoriously inefficient, due to the peculiar cycle of operation. Each cylinder must be capable of starting the heaviest load, which means that the combined engine is considerably larger than necessary. This permits of rapid acceleration and a short quick cycle is therefore possible.

Indicator cards show that during the accelerating period the cards are practically square, after which drifting takes place until the braking period. The efficiency is naturally low and considerable power is saved by the use of electric hoists. With an electric motor uniform torque is obtained and an excess of capacity is not required. The efficiency depends somewhat on the electric system used, but in any case the efficiency is much higher and cost of operation is much lower than with the steam hoist.

This is clearly shown by some actual tests extending over a period of two years at one of the mines of the Lehigh Coal and Navigation Co. The results of the tests were published in a paper entitled "Economy of Electricity Over Steam for Power Purposes in and About Mines," by R. E. Hobart, mechanical superintendent of the Lehigh Coal and Navigation Co., at the February, 1918, meeting of the American Institute of Mining Engineers.

Cutting and punching machines may be of the compressed-air type, but a large proportion of these machines are electrically driven. Operating compressed-air cutting or punching machines at night is as a rule not economical, as it entails running large compressor units which may not be used for any other purpose at the time, resulting in inefficient operation. With the electric cutting machines, however, the power-producing apparatus can be operated economically at light loads and, as before stated, the principal saving effected by night operation is in the improvement of the load factor.

The methods to be employed for the elimination of power losses may be divided into two classes, one which will produce immediate results while the other, by reason of the equipment and changes involved, may require several months.

Under the first class may be mentioned: Regularity of inspection and repairs to power plant equipment; instructions to firemen, engineers and electricians; scheduling the use of power to improve the load factor; improving the transmission and return circuit conditions; changing time of starting day shift. Under the second class may be mentioned: Installation of new equipment; changing over to electric operation; changing over to central station power; providing spare equipment; providing spare parts for use when necessary.

PERSONNEL OF THE FEDERAL FUEL ADMINISTRATION, WHICH IS SHORTLY TO WIND UP ITS AFFAIRS

Preservative Treatment of Mine Timbers as a Conservation Measure*

By KURT C. BARTH
Chicago, Ill.

SYNOPSIS — *Wood preservative may be profitably applied to a large proportion of the lumber and timber used by mining companies. Three distinct methods of application are available—the pressure, immersion and brush processes—the choice depending upon circumstances. Timbers treated with preservative and then coated with gunite should be nearly fireproof and of almost indefinite life.*

WOOD preservation applied to a large portion of mine construction is an important economy and a conservation measure of considerable magnitude. Preservative treatment of mine timber, for underground as well as surface structures, must be practiced systematically and consistently in accordance with established principles and in a manner which will assure the most practical results.

The object of preservative treatment is to increase the natural life of structural wood to equal the mechanical life, or to render it fit to serve the purpose intended for the full period of its mechanical usefulness. Thus, in every instance where decay may be expected to weaken and render the timber or structure unfit to perform the required service, necessitating repairs or replacement before its usefulness has ceased, the logical thing is to employ available means of counteracting such destructive influences—namely, to employ proved methods of retarding the development of fungous growths.

The fundamentals of wood preservation are definitely established. It only requires their application to the case in hand to ascertain whether the advantages to be derived from such practices warrant the expense of employing methods of preservative treatment, and exactly which methods or processes are most practical in the circumstances.

Consequently, the first step must be a careful analysis of the conditions directly or indirectly related to the matter, and their relative influence upon the determining factors. Practically, each mining property presents an individual problem, and particularly does this apply to coal mines. The suggestions contained herein must, therefore, be quite general, but their specific application requires merely suitable modifications to meet the conditions encountered.

Preservative treatment of timber is a conservation measure for several reasons: It permits the utilization of less durable species of wood for purposes where, if untreated, it would not be worth the labor of placing. (2) It prolongs the life of such timber until it equals and usually exceeds that of the most durable commercial species when used untreated. (3) It conserves labor and releases for productive employment men engaged in the nonproductive capacity of replacing decayed timber. (4) It conserves the timber supply by reducing considerably the demand for repairs and replacements because of decay. (5) It increases the available supply of timber for other uses now possibly restricted because of the huge demands for mining purposes. (6) By permitting the employment of timber obtainable in the immediate vicinity it lessens the demand upon transportation facilities for moving timber from distant sources of supply. (7) It conserves iron and steel products by the judicious substitution of wood for structural purposes, without sacrificing reasonable permanency.

These facts may not all apply in every case. As previously stated, they are general yet nevertheless of sufficient importance under present conditions, and in their relation to the period of reconstruction which is before us, to alone make imperative the adoption of wood preservation as a policy.

Economic Phases of Timber Treatment

The economic phases of the matter are more pertinent, in that they permit visualization of the dollars and cents that may be saved. These may be enumerated as follows: (1) A saving of material, equal to the increased service obtainable from treated timber, and accessories used in construction. (2) Saving of the labor required for repairs, the handling of material, its manufacture, transportation, etc. (3) Saving of equipment and tools required for repairs or replacement of timber and structures. (4) Saving of time and the loss due to interrupted production necessitated by repairs which must be made where operations are continuous. (5) Saving in overhead and the expense of supervision and engineering often required for underground repairs or replacements. (6) A lower annual cost of treated underground timbering and wooden surface structures as compared with untreated wood, and a proportionate reduction of the cost of production per ton.

In any case where preservative treatments are at all advisable there will always be found a considerable net saving. It would be possible to present an interesting hypothetical case, but such figures would only be relative at best, and perhaps of little use for our present purpose, without a direct application to the particular conditions.

The practicability of preservative treatment is dependent upon a number of factors of varying values which must be carefully defined and translated into a simple mathematical problem of cost versus profit. These are primarily the following: (1) Species of wood to be employed, its physical fitness for the purpose and its cost. (2) Where local timber is to be employed, facilities for manufacturing, including peeling and seasoning. (3) Durability under prospective conditions of service. (4) Character of service in which timber and

*Paper for presentation before meeting of the Coal Mining Institute of America at Pittsburgh, Penn., Dec. 5, 1918.

lumber are to be employed, or the type of structure. (5) Average period of mechanical usefulness under existing and probable future conditions. (6) Average number of years additional service practically obtainable by the elimination of decay. (7) Cost of treatment required to obtain desired increase in life. (8) Annual cost of untreated timber or structure. (9) Annual cost of treated timber or structure. Such an analysis would answer the important question of whether treatment would pay.

The next step then would be to determine the most suitable method or process of treatment. Herein, as in most subjects, exist differences of opinion; but fundamentally there can be none, in that any treatment to be worth while must attain the desired object, which is to assure a sufficient saving to warrant its employment.

Under the stress of operating conditions methods must be devised and employed which often are far from the ideal, and when the most efficient is not available or too costly for the purpose, one less efficient but still *sufficiently efficient* to be worthy of consideration must be made to answer. To discard preservative treatment simply because, for instance, timber impregnated by the pressure process is not obtainable, or too costly, is illogical, since for just such conditions the non-pressure processes have been developed, and with proper safeguards are entitled to equal recognition.

Processes of Preservative Treatment

The standard processes of treatment are divided into two groups. Group A—Pressure Processes—includes: (1) Full cell treatments; that is, impregnation of timber to a predetermined extent, leaving the wood cells full of preservative, applied in retorts or cylinders under artificial pressure, with (a) creosote oil, (b) zinc chloride, (c) solution of zinc chloride and creosote. (2) Empty cell treatments; that is, impregnation of timber to a predeterminated extent, in retorts or cylinders under high artificial pressure, and removal of the surplus preservative, leaving the wood cell walls coated and the cells more or less empty.

Group B—Non-pressure Processes—Includes: (1) The open tank process; that is, the impregnation of timber in open tanks, or vats, under atmospheric pressure only, by complete submersion for varying periods in alternate hot and cold (or cooling) baths of refined coal-tar creosote oil. (2) Surface treatments; that is, several successive applications of refined coal-tar creosote oil to timber at points of contact, or over the entire surfaces by (a) brush treatments—two or more paint coats; (b) properly designed spraying machines; (c) dipping, or short immersions in the heated creosote.

A further grouping will divide all treatments into two classes: (1) Impregnation processes, including both pressure and non-pressure methods by which an adequate penetration of the preservative is obtained. (2) Surface treatments, the purpose of which is to retard decay at certain points exposed to a greater degree than are other portions.

Each method of treatment enumerated has definite limitations and advantages, and the selection of one must depend strictly upon meeting the requirements of the case in hand as may be dictated by an analysis of the governing conditions.

Sawed timbers which when in service are exposed to severe mechanical wear must be impregnated with the preservative to an adequate depth in order to present an unbroken barrier to attack by fungous growths should abrasions and ordinary checks occur.

Round timbers, having an ordinary sap ring, when properly seasoned, can usually be satisfactorily treated by the open tank process, as the sap wood of practically all commercial species is readily impregnated.

Impregnation processes are always advisable when the maximum increase in the natural life of structural wood is desired, and in every instance where non-durable species of wood are employed. Timber surface structures in which durable grades are employed should be given at least a surface treatment at points of contact, either during construction or previously.

Structural wood should be seasoned air-dry before treatment, particularly when non-pressure processes are to be used. If green, artificial seasoning may be done in connection with pressure treatment, but seasoned timber is always preferable. For mining purposes, especially for underground uses, the timber must be peeled immediately after cutting, and then seasoned for at least 30 to 90 days, depending upon weather conditions and the season of the year.

The analysis previously outlined includes the selection of the preservative. This is, undoubtedly, by far the most important factor in determining the efficiency of any method of preservative treatment. Herein also there exists a great variety of opinions, in which numerous theories play a more or less important part. However, practical experience gained in the commercial practice of wood preservation during nearly four score years has clarified the situation to such an extent that we can today deal in definite values and the knowledge of actual performance. Primarily, we are concerned with two products—coal-tar creosote oil and zinc chloride.

Both of these preservatives have been in use sufficiently long to establish their relative merits beyond the possibility of detraction. Recently experiments with sodium fluoride for the treatment of underground timbers has given promising results, but the latter product has not yet established the reputation or record of other salts such as zinc chloride. For surface structures especially, and for by far the majority of all purposes, coal-tar creosote oil is eminently the most efficient preservative. There is no record of failure of properly creosoted timber.

Such minor points as appearance and odor have been much discussed, and until recently the wide-spread impression that the employment of creosoted timbers increases the fire hazard has been an obstacle to the general introduction of creosoting. But these objections have been overcome and removed by proper education and changes in methods. Those who have thoroughly investigated the matter realize that creosoted timber properly handled is not a fire hazard—on the contrary, dry creosoted wood is less inflammable than untreated wood.

Howard F. Weiss, in his book, "The Preservation of Structural Timber" (page 192), cites an experience where after a fire in a mine the untreated props were destroyed while the creosoted timber was merely slightly charred on the surface but still serviceable. Wood freshly impregnated is more inflammable than

before, but no matter for what purpose it may be intended, treated wood should always be thoroughly dry before placing.

Numerous mines have used creosoted timber for shaft lagging, shaft timbers, head frames, gangway and main entry sets, and so far I know of no record of fire or casualty directly or indirectly charged to the presence of creosote in the timber. It would seem therefore that much of the prejudice against creosoted wood for mine uses is really without foundation in fact, particularly where modern methods of fire prevention prevail.

Extensive experiments in fireproofing underground timbers in both coal and metal mines by mechanical application of concrete coatings has given considerable impetus to this method. It has occurred to me that a combination of creosoted timber and this "cementation process" would be an admirable type of permanent construction. It is practically impossible to absolutely exclude air and moisture by such a coating, consequently decay can be expected to progress unhindered, and possibly more rapidly, causing the weakening and collapse of the timber without the opportunity of detection in time to perhaps avoid accident.

Untreated Timbers Fail Rapidly

Numerous instances have been observed where untreated electric power transmission poles set in concrete, nailing strips for floors partially embedded in concrete, as well as columns entirely encased in cement or plaster, have failed more rapidly than would otherwise have been the case. In consequence, when such type of construction is necessary the best practice requires preservative treatment, mostly surface applications of refined creosote of all parts partially or entirely inclosed. For instance, if the timber for shafts and permanent workings, or where the period of mechanical usefulness would warrant, were creosoted by the open tank process, which could be done at comparatively small expense at the mine, and when placed coated with ¼ to ½ in. of cement and sand, decay would be practically eliminated; and the fire hazard, if existent, greatly reduced if not entirely removed.

This is merely a suggestion which I would be pleased to carry out in an experiment in coöperation with any mine operator interested. The theory is that by utilizing native round timber properly treated the necessary mechanical support is obtained, and that with an application of "gunite" merely sufficient to act as a fire retardant coating, the highest factors of safety and economy are combined.

Wood is still extensively employed for surface structures, and undoubtedly will be for some time to come, particularly now and during the immediate future, when steel and iron will be in such great demand as to necessitate its conservation wherever possible. In this field the employment of non-pressure processes is especially applicable. Repairs due to decay of timbers in exterior structures largely result from the development of fungi in inclosed parts or at points of contact. Therefore, application of surface treatment to timbers previous to assembling will retard decay at the most vulnerable points and increase the life of the entire structure.

Many wooden tipples and shafthouses have been so treated, and after erection refined creosote found further employment as a substitute for paint because of its lower cost and greater preservative value. Such practice is not confined to mining operations, but is extensively used by other industries. Trestles of various types, which are of a semi-temporary nature, that is, the mechanical period of usefulness is set at 15 years or so—have been brush-treated or sprayed at points of contact in order to increase the natural life of the timber to equal the mechanical life desired. Telephone and electric poles are brush-treated with excellent results. Mills in which manufacturing processes create conditions favorable to the development of decay have installed tanks for treatment of lumber and timber for miscellaneous uses.

The development and promotion of non-pressure processes of treatment, which are entirely dependent upon the use of refined coal-tar creosote oil, have made it possible for the average consumers who cannot equip themselves with apparatus necessary to impregnate timber by the pressure processes, to enjoy the full benefits of wood preservation to the degree in which they conform to the simple but necessary requirements. It is now possible for every user of wood, large or small, to avoid the waste of permitting it to decay. Those who are not informed on the subject can readily become so through various sources. The United States Forest Service maintains a research department at the Forest Products Laboratory in Madison, Wis., which deals entirely with wood preservation problems and whose bulletins and reports are available to the public gratis. Manufacturers of preservatives employ experts to promote their proper use and to aid consumers in solving problems.

The coal industry has a very particular interest in the development and popularization of wood preservation because of the normally increasing consumption of coal-tar creosote oil, largely a byproduct of coke making. Therefore, adoption of wood preservation is of twofold benefit in that it reduces considerably the high expense of timber replacement due to decay and furthers the expansion of an industry which consumes a large volume of one of the chief byproducts of coal.

Will Increase Coal-Loading Facilities a Hampton Roads

Eleven DeMayo bunkering machines are to be installed at Hampton Roads by the Port and Harbor Facilities Commission of the Shipping Board. Six additional coal barges with an aggregate capacity of 6500 tons are to be put in service. During the war, Hampton Roads has been the most important turn-around point on the Atlantic coast, with the exception of New York.

Five of the DeMayo machines have been constructed by the American Car and Foundry Co., of Berwick, Penn., and have been ordered to be shipped immediately. Three used machines were purchased in New York and are about to be shipped. Three more new machines have been ordered from a firm in New York.

These machines are capable of handling 75 tons of coal an hour, and it is intended to install two of them on each barge. The maximum capacity of the machines is rarely utilized, however, because it is impossible to trim the coal in the ship as rapidly as it can be turned into the bunkers. This trimming usually restricts the work of bunkering to between 25 and 50 tons an hour for each machine.

An Unusual "Bounce" Condition

By A. C. WATTS
Salt Lake City, Utah

SYNOPSIS—*"Bounces" occurred with annoying frequency in a heading driven in virgin territory and under comparatively light cover. This condition was somewhat mystifying until a fault was driven through and an analysis of conditions made. Beyond this fault, which is the second pierced by the development of this entry, no bounces have occurred.*

DURING the driving of a slope in one of the Utah mines of the Utah Fuel Co., considerable trouble was experienced from "bounces," the occurrence of which could not be explained by the commonly accepted theories which have heretofore satisfactorily accounted for such phenomena as had occurred in other parts of the same mine and in other mines of the same district. Heretofore bounces had taken place in pillar workings under heavy cover, but in this instance the workings were in virgin territory, several hundred feet away from room workings and 1500 ft. distant from the nearest pillar operations.

The first indication of trouble was the sloughing of the coal from the ribs of the entry, particularly the right rib facing down pitch. As the entry progressed the forces became greater and the coal from the ribs was broken up and thrown out with considerable force. As the entry was driven still further down the pitch, the roof coal would be broken down also and finally coal would be thrown from the face as far as 10 ft., extending the face as much as 5 ft. This face coal would be broken to pea size and smaller.

The width of the entry was widened in places to 16 ft. from an original width of 8 to 10 ft. To protect the entry and workmen, a concrete wall from 9 to 12 in. thick, reinforced with old rail, was built along the rib from which the coal sloughed most freely. This wall extended down the slope for 200 ft., and the rest of the entry was heavily timbered and lagged on ribs and roof. Finally work was abandoned temporarily in the main slope and an effort was made to advance the back slope ahead of it, in the hope that the pressure on the main slope would be relieved as the back slope had theretofore been comparatively quiet.

In driving the back slope the width was kept at 8 ft. and the height 6 ft., both sides and roof being heavily timbered and lagged. Although several bounces took place while driving the back slope, it was successfully driven down 150 ft. without accident until a fault was encountered. This fault, in connection with other conditions that will be described later, satisfactorily explained the cause of the bounces. The unexplainable feature is the entire absence of bounces in the level entries driven to right and left off the slope at the seat of trouble.

At the beginning of the explanation it must be stated that three conditions, which have proved conducive to bounces in this district, were present in this instance. They are (1) heavy cover, (2) the nature of the cover and (3) a hard, brittle coal. The cover here, as shown by the profile (Fig. 1), was 1500 ft. thick and was rapidly increasing as the slope came under the crest of a divide. This cover is made up to a large extent of massive sandstone, aggregating in some places 500 ft. thick. The sandstone is very cohesive and does not break and cave easily. The sloughing and bouncing of the ribs of the slope was aggravated by the butt cleavage of the coal, which ran nearly parallel with the direction of the slope and inclined 30 deg. off the vertical from the top of the seam. Ordinarily the butt cleavages in this district are not very pronounced, but bending action, which will be explained later, had made them at this point quite prominent.

So far conditions were ideal for bounces if the workings had been pillar workings, but other reasons had to

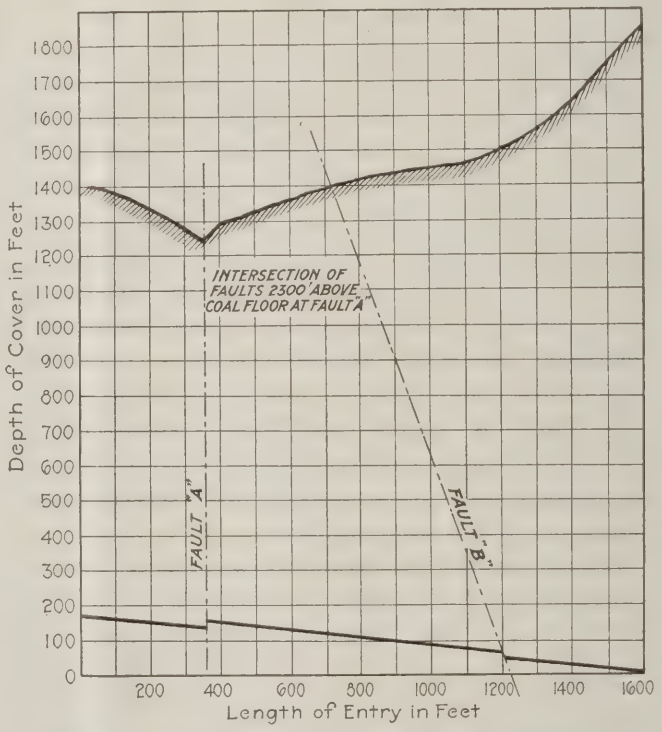

FIG. 1. PROFILE OF COAL BED AND SURFACE

be sought to explain why bounces should occur in an entry entering an apparently solid block of coal and territory never before worked. After the fault (fault *B* in Fig. 2) encountered in the back entry had been proved, it was found to be a downthrow of 17 ft., bringing the floor of a 5 ft. 3 in. upper seam to the same level as the 9 ft. 9 in. bed being worked. Further up the entry 840 ft. an up fault (fault *A*) of 18 ft. had been encountered. This fault (*A*) was practically perpendicular whereas the lower fault (*B*) inclined toward it 20 deg. Fault *A* crossed the slope at approximately 90 deg.; fault *B* at approximately 67 deg. The strata between these faults had been thrown off the normal pitch of the measures so that the normal pitch was increased in the fault block by 1 per cent.

These two faults formed a wedge with the apex above the surface and thus left an unsupported block between them. Fault *B*, if continued to an intersection with the perpendicular fault *A*, would intersect it about 2300 ft. above the coal floor. The surface profile shows a marked depression directly over the extension of fault *A*, which depression undoubtedly marks this fault on the surface. The Government topographical map shows a canyon starting at this point.

As stated above, the frequency and force of the bounces increased as the entry was driven downward. The reason for this became apparent when the lower fault was struck and developed and a study made of the fault block in connection with the overlying strata. A geological section shows the two coal beds at this mine to be between heavy blocks of massive sandstone analogous to a brittle substance between two grindstones. The faulting forces had tilted the fault block out of conformity with the balance of the area, and probably there is still some tension at this particular section.

Furthermore, the inclination of the fault block tends to increase due to the pitch of the lower fault, which forms a slippage plane. This is further aggravated by the weight of the overlying strata, which are sheared by both faults clear to the surface and thus rest directly

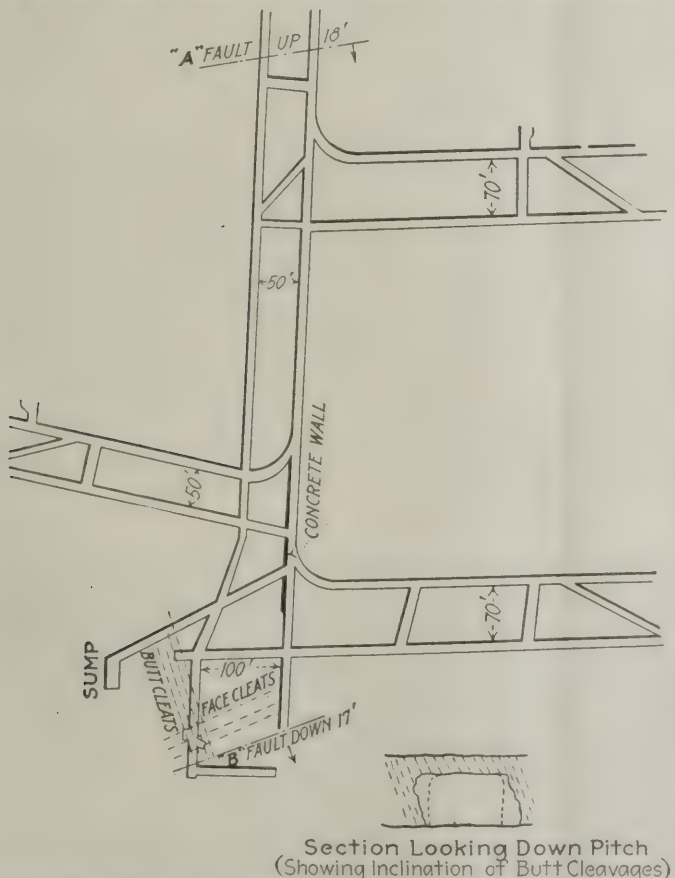

FIG. 2. PLAN OF WORKINGS AND LOCATION OF FAULTS

on the wedge-shaped fault block. Thus two forces are working on the comparatively soft and brittle coal. Naturally this pressure would relieve itself as soon as an opening was made in the coal. No bounces occurred in the back entry when driven below the fault, and it is not expected any will occur because solid ground is being entered; and the strata overlying the coal is better supported and not subject to stresses as found in the fault block.

It is interesting to speculate on the reasons for these faulting and bending actions. G. B. Richardson, in United States Geological Survey Bulletin No. 371, describes the structure of the Book Cliffs coalfield in which this mine is located as follows:

The strata of the Book Cliffs coalfield, forming as they do part of the southern margin of the Uinta synclinal basin, dip gently northward. The dip is not uniform, how-

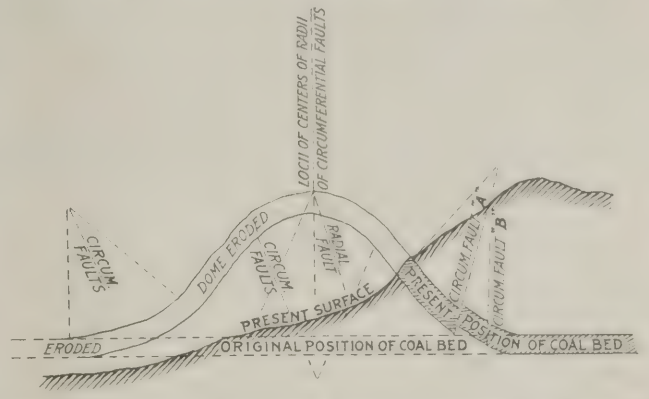

FIG. 3. ILLUSTRATING THE DOME THEORY OF FAULTS

ever, for this area, besides being included in the zone of folding of the Uinta Mountains and the Uinta Basin, is affected by the uplifts which produced the San Rafael Swell and the Uncompahgre Plateau. That part of the Book Cliffs coalfield which is included in the present report is gently warped, the eastern part constituting the end of a low, northward-plunging anticline, and the western part the end of a northward-plunging syncline. Conforming with this structure, the irregular S-shaped outline of the cliffs coincides with the strike of the rocks. There are, also, local faults of small displacement.

The district has also been described as the remnants of a great dome, the central portion of which has been eroded by the Price and San Rafael rivers by whose waters in ages past, geologists estimate, 160 billion tons of coal have been carried into the Gulf of California. Whichever it was, dome or a great warped syncline, the faulting action would be somewhat similar and each would explain the conditions that are found.

Accepting either the "drift" or "in situ" theory as correct for the formation of the coal, it was laid down in vast flat beds. At one part of these beds, which has since been covered with thousands of feet of sedimentary deposits, a vast dome had been lifted or a great warped fold had been made. This lifting action of the dome would develop two different lines of faulting: one radially from the center of the dome and the other circumferentially around the dome. There would be really two series of circumferential faults: one with the center of the dome for a center, and below the surface, and one centering toward or above the surface. These fault planes would form great, more or less, regular cylinders extending around the dome and with axes common with axis of the dome (see Fig. 3).

Evidences of the first series of circumferential faults are lacking due to erosion which has taken away the crest of the dome, but the latter series of circumferential faults, which mark the bend in the strata where they begin to resume their original flat position, is still in evidence and it was a combination of two of these faults that produced the condition so conducive to the bounces experienced.

Radial faults extending from the top center of the

dome outward would gradually become less in magnitude of throw as the distance from the top of the dome increased. These faults would mark changes in the direction of the strike which are noticed in this district.

If the synclinal theory is accepted, we would find the faults which correspond to the circumferential faults of the dome theory extending in lines parallel with the axis of the syncline. Where there was a bend in this axis, or a warping, the faults would be thrown diagonal to the parallel direction and faults more or less perpendicular to the axis would be possible. Fig. 4 plainly shows this theory to be plausible in the district. The strike of the strata has changed approximately 15 deg. and this was accomplished gradually without the appearance of radial faults sufficiently strong to give abrupt changes in strike and prove the dome theory. However, it must be said the structure of the coal deposits has not been thoroughly studied as a whole, and the various districts in which mining is being prosecuted have not been completely correlated. Also, that the district under discussion comprises only about three miles of a territory that embraces hundreds of square miles. It would thus not be safe to say that conditions which seem to prove one theory in this district prove it for the whole.

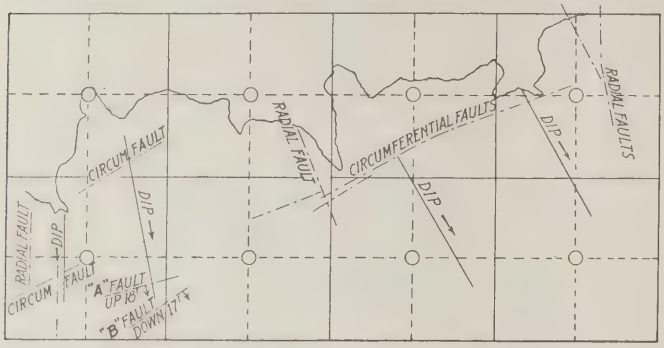

FIG. 4. GENERAL TREND OF FAULTS AND PITCH OF STRATA IN VICINITY

It is apparent that the two faults making an unsupported block so shaped that movements were invited, so to speak, were the main cause of the bounces. The change in the direction of the strike caused a bending stress in the strata which was not relieved by radial faults and only partially relieved by fault *B*. This bending stress is still potential and is manifested by the exaggeration of the butt cleavages and partially in the bounces.

Wireless Telegraphy

"It's all right to tell your wife some things, but one ought not to tell his wife everything."

This bit of philosophy fell from the lips of the president of one of the local unions of the United Mine Workers at a scale convention held in a large mining town recently. After stating this truth, the president of the union explained what was in his mind.

The financial secretary of the union at a certain mine had been given the password of the union, which is very sacred. The financial secretary told it to his wife after swearing her never to reveal it. (Is there any use of continuing?) The secretary's wife told the pit boss' wife and she——. The president reported the election of a new financial secretary.

Legal Department

EMPLOYEE INJURED WHILE RIDING ON CARS—The Alabama statute which forbids mine employees to ride on haulage trips in going to and from their places of work has no application to tramways outside of mines, disconnected with such ways in mines. Hence the statute did not apply to the case of a miner riding on a tram car used on the surface to carry coal from a stock pile to the point of loading on railway cars. (Alabama Supreme Court, Monte-Vallo Mining Co. vs. Underwood, 79 Southern Reporter, 453.)

COAL FREIGHT RATES—The North Dakota Supreme Court has denied the right of a railway company to recover the excess of claimed reasonable rates on intrastate shipments of coal above statutory rates against a shipping operator. This suit—Minneapolis, St. Paul & Sault Ste. Marie Railway Co. vs. Washburn Lignite Coal Co., 168 Northwestern Reporter, 684—was based on compensation for carrying coal while litigation was pending to determine the validity of an act passed by the North Dakota legislature in 1907, fixing maximum rates for the carriage of lignite coal. The rates were ultimately found by the Federal Supreme Court to have been confiscatory, and the railway company sought to recover the excess of what it conceived to be a reasonable transportation charge. The precise point decided by the North Dakota court in this suit is that the mere fact that a statute prescribing freight rates is finally held to be invalid as being confiscatory does not entitle carriers to enforce reparation against shippers.

NEGLIGENT SALE OF DYNAMITE — Defendant coal-mining company kept on hand a supply of dynamite to be used by the miners in its employ whenever necessary to do any blasting, and sold it to the miners as they called for it. Two grades containing 40 and 60 per cent. dynamite respectively were kept for sale. Plaintiff, a miner, called upon defendant's storekeeper for a supply of the less explosive grade, and, supposing that he had obtained it, used the dynamite, tamping it in a drill hole in the manner in which he was used to safely handle the lower grade explosive. An accidental explosion resulted, rendering plaintiff permanently blind. In affirming judgment for $10,000 in favor of the injured man, the Kansas Supreme Court decides that the jury's finding of these facts establishes actionable negligence on the part of the defendant, acting through its storekeeper. (Terleski vs. Carr Coal Mining and Manufacturing Co., 173 Pacific Reporter, 8.)

MEASURING DAMAGES FOR PERSONAL INJURIES—DELEGATING EMPLOYER'S DUTY—In reversing judgment which had been awarded in favor of a miner on account of injuries sustained by him through a fall of roof in the mine of the defendant in which he was working, the Alabama Supreme Court lately laid down the following rules governing the measure of damages to be awarded in Alabama when liability for personal injury is established, and the question whether an operator may delegate performance of certain acts to employees and thereby relieve himself from liability for any negligent performance of the delegated duties: "The measure of compensation to an injured employee is determined by the evidence (which may include mortuary tables, to show the probable duration of life) upon such factors as the age of the person, his business habits, industry, and sobriety, usual earnings, skill, and whatever other relevant facts of the case would aid the jury in arriving at a fair and just compensation for his sustained pecuniary damages. . . . The duty of the master, under the common law, is to exercise reasonable care to furnish the servant a reasonably safe place to work. This duty cannot be delegated. Yet the master may delegate the duty of exercising reasonable care to *maintain* such a place of work in a reasonably safe condition; and if such place becomes unsafe through the negligence of the servant to whom such duty is delegated, the master is not liable." (McCollum vs. South Brilliant Coal Co., 76 Southern Reporter, 901.)

The Hazard Coal Field

By P. M. SHERWIN
Blue Diamond, Ky.

SYNOPSIS—*Hazard coal is known chiefly for its hardness and low ash content. The region where it is produced is rough and mountainous, and presents many contrasts of old pioneer days and modern civilization. Much development work will doubtless take place in this field soon, and its future would appear to be assured.*

AMONG recently developed coal areas in the United States the Hazard field of eastern Kentucky is probably the most important as to present output as well as future prospects. Named after Hazard, the county seat of Perry County, it includes all the mines on the North Fork of the Kentucky River and its tributaries from Jackson to Whitesburg, Ky., a distance of about 80 miles. The territory is served by what was originally the Lexington & Eastern Ry., but is now a branch line of the Louisville & Nashville R.R., extending from Lexington to McRoberts, a distance of about 200 miles. Near McRoberts, 20 miles above Whitesburg, are the mines of the Consolidation Coal Co. and the Elkhorn Coal Corporation. But as these companies operate in the Elkhorn seam they must properly be designated as belonging in the field of the same name.

The railroad had reached Jackson early in the eighties, but there it stopped for nearly three decades until the rapid development and heavy demand for Elkhorn coal induced the Louisville & Nashville to extend its Jackson line in an effort to tap this rich field. At the time of its building little was thought of the coals in the Hazard field. However, great difficulties presented themselves to the penetration of the mountain ranges by the railroad builders, and when the headwaters of the Kentucky River were reached at McRoberts, it was decided to make this the end of the line. Thus it happens that the Hazard field today furnishes the greatest percentage of outgoing tonnage.

Prior to the completion of the railroad in 1912, the mountainous regions comprising Perry and Letcher Counties were known to the rest of the United States only by the stories of Fox and other writers. Hazard in 1912 had a population of 500, mostly housed in small shacks and log cabins. The next census will show 5000 people, living in a town with modern streets, electric lights and water-works.

This shows truly remarkable progress, yet many circumstances tend to remind one still of the olden days. A few miles away we might find ourselves at some lonesome log cabin where even a hint of our modern civilization would seem far-fetched and out of place. The bloody family feuds and the battles between revenue officers and moonshiners have grown scarce, it is true, but every native still "totes" his gun and shootings are even yet fairly common; also many are the secret stills where corn mash is turned into the forbidden "moonshine."

In common with other mountainous and remote sections the country is quite crude. There are no roads worthy of the name. The native is still satisfied to ride to the postoffice, the store or the mill on his trusty mule. He is apt to regard the newcomer with suspicion and universally designates him by the name "furriner."

Slowly, however, a new spirit is penetrating from the mining camps into the distant, narrow hollows. When the native workman leaves the camp in the spring to plant his corn on the steep hillsides, he takes with him little bits of culture which eventually will work as the leaven in the loaf. Nevertheless, the most common habitation is still the log cabin. Even now the weekly supply of corn is taken to the mill strapped behind the saddle and the jug of illicit whiskey is yet found in the hollow tree in exchange for so much legal tender. Slowly modern ways are penetrating from the valley of the Kentucky River to the most far-flung ridges of the Cumberland and Black Mountains. The coal production of this region in five years has risen from zero to nearly 20,000 tons daily. Given the men necessary (and it is not a fanciful prophecy) five years hence the output will be more than doubled.

HAZARD COAL GOING THROUGH THE SCREENS IN THE TIPPLE

Geologically the field belongs to the Appalachian coal-bearing measures. It contains three workable beds above the river valley. No. 3 seam is about 25 ft. above the river at Hazard. It is a little over 2 ft. in thickness, and con-

tains dirty coal of no commercial value. No. 4 seam, showing 48 in. of clean coal, is at tipple height and is probably of greatest importance of any coal-bed in the field on account of its great consistency as to thickness and quality as well as extent in area. Seams No. 5 and 5A are of no value. Two hundred feet above No. 4 seam we find No. 6, with from 65 to 70 in. of coal, but containing a 4-in. band of jack rock 10 in. from the bottom. No. 7 seam is about 60 ft. higher and averages 72 in. of coal, but also carries a band of jack rock. On account of the rough nature of the country, showing heavy erosion and abounding in deep and numerous valleys, the Nos. 6 and 7 mining areas are much cut up. This renders a hard and fast system of development difficult. However, all the coal is universally mined on the room-and-pillar system, no long-wall to the best of my knowledge being employed in any of the mines of this region.

It is principally due to the No. 4 bed that the fame of Hazard coals spread so rapidly and was followed by an influx of capital and consequently a still more rapid development. This coal was first shipped to the Northwestern market and gained fame as a high-grade domestic fuel, as it is an extremely hard coal of low ash content. This quality strongly appealed to users of anthracite.

As a general rule, and on account of the extreme steepness and height of the hills, the companies operating the upper seams use retarding conveyors to bring their product to the railroad cars. A few plants employ monitors. Usually the coal is screened to three sizes. There are in all about thirty companies, with varying capacities in operation, along the North Fork of the Kentucky River. Seven more are located on First Creek, a tributary, 5 miles below Hazard, with a daily output of 100 cars. Ten are being opened on the new Lots Creek branch of the Louisville & Nashville R. R., with a proposed total daily capacity of 200 cars. These mines will ship with the opening of the railroad early next year. Tipples and towns have been built, headings are being driven and 50,000 tons of coal are mined and stored, waiting for the coming of the cars to help alleviate the nation's fuel shortage.

The Columbus Mining Co., the Daniel Boone Coal Co., the Blue Grass and the Hazard Coal companies are all operating in the immediate vicinity of Hazard and work seams Nos. 2 and 3 simultaneously.

One mile above Hazard at Lothair is the plant of the Kentucky River Power Co. It is a modern turbo-electric steam plant developing 6000 kw. It supplies all the larger mines in the district and furnishes light and power for the City of Hazard. Only one power plant is now in operation here. The power house is economically situated at the tipple of the Kentucky Jewell Coal Co., the slack being directly elevated from the screens to the overhead bunkers by bucket conveyors. In order to guard against interruption of the service on account of any failure of this particular mine an auxiliary conveyor can furnish coal from a track hopper.

There are two 1500- and one 3000-kw. turbines installed in this plant. At present the company supplies about twenty mines within a radius of 20 miles, with as many more new operations under contract. There are 60 miles of high-tension transmission line, carried on wooden poles; at the numerous river crossings, steel towers are being used. The current is three-phase, alternating with a voltage of 33,000. At the mines this is stepped down in oil transformers to 2200 volts and delivered at this potential to the coal companies.

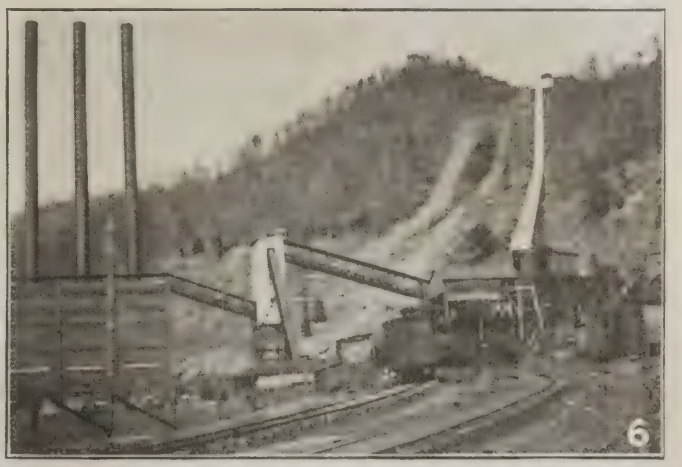
Several coal companies with modern plants are located along the river as far as the mouth of Carr's Fork. Here a branch of the Louisville & Nashville R. R. 8 miles long is under construction. This no doubt eventually will extend the full 28 miles of this not inconsiderable water-course. Rockhouse Creek at Blackey and Smoot's Creek at Roxana are the starting points for other branch lines, with mines operating and under construction. Several of the mines carry their coal across the river by means of cableways, but none of these are large producers. Mace's Creek, Leatherwood and Kingdom Come offer a vast undeveloped region and will no doubt see the building of branch lines soon.

INTERIOR OF BOILER HOUSE AND TURBINE ROOM OF KENTUCKY RIVER POWER CORPORATION

Forty-five miles above Hazard lies Whitesburg, the county seat of Letcher County. The coal measures rise considerably faster than the river and at this point the lower seams of the Elkhorn field are exposed, thus taking the place of the Hazard coals which have mostly been eroded away with the tops of the mountains.

The Elkhorn coals, usually considered as belonging to the Big Sandy field, are much higher in volatiles and remarkably low in sulphur, and therefore form an excellent byproduct fuel.

The Lexington & Eastern, now known as the Eastern Kentucky Division of the Louisville & Nashville, is



VIEWS OF SURFACE PLANT AND MINING OPERATIONS IN THE HAZARD COAL FIELD

1—Carrs Fork Valley. 2—Daniel Boone Coal Co., No. 4 Seam Mine. 3—Louisville & Nashville yard at Hazard. 4—Partial view of Hazard. 5—Blue Grass Coal Co. 6—Kentucky Jewell Coal Co. and Kentucky River Power Co. 7—Blue Diamond Coal Co. 8—Hazard Jellico Coal Co.

essentially a coal road, the only other outgoing commodities being hardwood logs and barrel staves. Enormous quantities of white oak and other valuable woods grow along the upper reaches of the river and its tributaries. To give some idea of the curvature of the railroad line, it may be stated that the distance from Ravenna to McRoberts by rail is 156 miles, while the airline distance is only about 75 miles.

The Hazard coal field has enormous possibilities for the future and the next few years should see the building of many more branch lines. This will be followed by the springing up of new towns and mining plants. A conservative estimate would place the daily capacity of this field at 35,000 tons, which should be reached in a few years time.

Chilean Coal-Mining Industry

The coal-mining industry of Chile dates back to 1849, when the first workings were opened. Development has been slow, compared with other comparatively new fields, like New South Wales and Japan. In Chile the development has been solely due to private enterprise, and consequently the progress has been slow and difficult. The first establishments, opening up near the shore, had the advantages of proximity to marine transport; but, on the other hand, the difficulties of mining under the sea with the reduced extent of foreshore for working shafts, etc., had to be surmounted.

The first mines to be exploited were those of Lota and Coronel. Later on the Lebu mines, followed by the establishments of the Arauco Railway and Mining Co., Ltd., and the Compania Carbonifera Nos Rios de Curanilahue. Some smaller companies like the Lirquen, Rosal, etc., at Penco, and the Victoria at Lebu are of more recent origin. In Punta Arenas there are some

Two Tables That Will Prove

In coking coal, it is frequently advantageous to know what will be the ash and sulphur content of the coke produced from a coal of given analysis. In the accompanying tables, Table I shows the per cent. of ash in coke made from coals of various percentage of volatile matter and ash; the number of pounds of coal required to make one ton of coke (Column 1); the per cent. of ash increase from coal to coke (Column 22); and the rules for and calculations relating to the compilation of the

Per Cent. of Ash in the Coal Charged:			2.50	3.00	3.50	4.00	4.50	5.00	5.50	6.00	6.50	7.00	7.50	8.00	8.50	9.00	9.50	10.00	10.50	11.00		

To find the percentage of ash remaining in the coke made from any given percentage of volatile matter and ash in the coal charged, follow the line corresponding to the given volatile matter to its intersection with the column corresponding to the given ash in the coal charged.

For example: Coal charged contains 30 per cent. volatile matter and 6.50 per cent. ash. At the intersection of line 14 with column 11 it shows 9.30 per cent. as the ash remaining in the coke.

Rule: To find the percentage of ash in coke from any given volatile matter and ash in coal, multiply ash in coal by factor in column 21 corresponding to the given volatile matter. For example: Coal 30 per cent. volatile matter, line 14, and 6.50 per cent. ash, column 11. Factor 1.43, line 14, column 21.

6.50 ash × 1.43 factor = 9.30 per cent. ash in the coke (nearly).

Rule: To find per cent. of increase from coal to coke, subtract 1 from factor. Example: Line 14, volatile matter, 30 per cent., factor 1.43, column 21.

1.43 — 1 = 43 per cent. ash increase.

Rule: To find per cent. of ash in coal from any given ash in coke and volatile matter in coal, divide ash in coke by factor.

Example: Line 14, column 17, ash in coke 9.30 per cent., line 14, column 21, factor 1.43: $\frac{9.30}{1.43}$ = 6.50 per cent. ash in coal.

Calculation to determine factor:

	Per Cent.	
Volatile matter.....	30.00	
Ash.....	6.50	Coke 70 per cent.
Fixed carbon.....	63.50	
	100.00	

100 parts coal contain 6.50 per cent. ash
70 parts coke contain 6.50 per cent. ash
100 parts coke contain $\frac{6.50 \times 100}{70}$ = 9.30 per cent. (nearly) ash in coke

Ash in coke = $\frac{9.30 \text{ per cent.}}{\text{Ash in coal} = 6.50 \text{ per cent.}}$ = 1.43 (nearly) factor.

older workings, which supply fuel to the steamers, and in the province of Valdivia there are some new mining developments at Millahuillin. The coal production up to, and including 1914, amounted to a total of 32 million tons.

This development has not been contributed to by the state, in the provision of a single railway, port works, or efficient geological survey of the carboniferous regions, to give the necessary impetus to the local industry. The high price of coal is in a great measure due to this neglect on the part of the government to encourage the national industries and the general prosperity. Now there is a persistent outcry against the "impoverishing of the country" by spending 30 to 35 millions of gold pesos annually on imported coal, and interested parties are clamoring for the imposition of import duties on foreign coals.

This is only aggravating the evil, by swelling the dividends of a few fortunate shareholders at the expense of the suffering public and increasing the price of an indispensable article, which is rapidly attaining to the rank of a luxury. What is absolutely necessary is good harbors, sufficient feeder railways running to the coast, and adequate rolling stock.

The Chilean coals all belong to the lignites of the tertiary period. The territory exploited up to date, which forms the productive zone of the carboniferous system of the provinces of Concepcion and Arauco, measures some 980 sq.km. This is comprised in a belt 90 km. in length by 10 to 11 km. wide.

The principal mining centers are the Bay of Arauco, where the workings of the Lota and Coronel companies are situated, and the eastern zone of the province of Arauco, at the foot of the Nahuelbuta cordillera. The workings of Lota and Coronel extend under the sea

Valuable in Coking Practice

table. Table II shows the volatilization of various percentages of sulphur during the coking process in coals of different volatile contents, the number of pounds of coal required to make one ton of coke and the rules and calculations relating to the compilation of the table. These tables are practically self-explanatory and require no further comment. They will be found useful not only to those who are already interested in coking but also to those contemplating going into the manufacture of coke.

TABLE II. THE VOLATILIZATION OF VARIOUS PERCENTAGES OF SULPHUR IN COALS OF DIFFERENT VOLATILE MATTER CONTENTS, DURING THE COKING PROCESS BASED ON VOLATILIZING 40 PER CENT. OF THE SULPHUR IN THE COAL

Line	Pounds of Coal Required to Make 2000 Pounds of Coke	Per Cent. of Volatile Matter in the Coal	Per Cent. of Sulphur Remaining in the Coke																		Factor	Per Cent. of Sulphur Decrease from Coal to Coke

Per Cent. of Sulphur in the Coal Charged:			0.80	0.85	0.90	0.95	1.00	1.05	1.10	1.15	1.20	1.25	1.30	1.35	1.40	1.45	1.50	1.55	1.60	1.65		

To find the percentage of sulphur remaining in the coke made from any given percentage of volatile matter and sulphur in the coal charged, follow the line corresponding to the given volatile matter to its intersection with the column corresponding to the given sulphur in the coal charged. For example, coal charged contains 30 per cent. volatile matter and 1.20 per cent. sulphur. At the intersection of line 14 with column 11 it shows 1.030 per cent., the sulphur remaining in the coke.

Rule: To find the percentage of sulphur in coke from any given volatile matter and sulphur in coal, multiply sulphur in coal by factor in column 21 corresponding to the given volatile matter. For example: Coal 30 per cent. volatile matter, line 14, and 1.20 per cent. sulphur, column 11, factor 0.858, line 14, column 21.

1.20 sulphur × 0.858 factor = 1.03 per cent. in the coke (nearly).

Rule: To find per cent. of sulphur decrease from coal to coke, subtract factor from 100. Example: Line 14, volatile matter, 30 per cent. Factor = 0.858.

100 — 0.858 = 14.20 per cent. sulphur decrease.

Calculation to acquire factor:

100 parts of coal contain:

	Per Cent.	
Volatile matter,	30.00	
Ash,	9.30	= coke 70 per cent.
Fixed carbon,	60.70	
	100.00	To make 2000 lb. of coke.

2000 ÷ 70 per cent. = 2857 lb. of coal required.

1.20 per cent. sulphur in the coal

34.284 total pounds of sulphur in the coal

40 per cent. of the sulphur volatilizing

13.7136 lb. of sulphur volatilizing

Lb. Lb.

34.284 — 13.7136 = 20.5704 lb.

$\frac{20.5704 \text{ lb.}}{2000 \text{ lb.}}$ = remaining in the coke, or 1.03 per cent. (nearly)

Formula for per cent. of volatilization.

Let a = Pounds of sulphur in coal charged;
b = Pounds of sulphur remaining in the coke;
x = Per cent. of volatilization.

$$\frac{a - b}{a} = x$$

$$\frac{a\ 34.284 - b\ 13.7136}{a - 34.284} = 40 \text{ per cent.}$$

Sulphur in the coke = 1.03 per cent.

Sulphur in the coal = 1.20 per cent. = 0.858 factor.

1200 to 1400 m., and it will be difficult to work more than 3000 m. from the coast. Notwithstanding this limitation, there is a capacity of 40 million tons for future production.

In the eastern region of the province of Arauco, which seems to be the same system as that of Arauco Bay, the coal beds are inclosed in 540 ft. of soil of a carboniferous formation, which includes the district from Peumo and Colico to Cullinco, through Carampangue, Curanilhue and Pilpico. This is where the mines of the Arauco Mining Co., Ltd., and the Ruos de Curanilahue Co. are situated. These are the best and most productive developments. The work is carried on under decidedly different conditions from those existing in the submarine workings on the coast. The entire output is transported by the Arauco Co.'s railway.

First Company Organized with British Capital

The Arauco Railway and Mining Co. was the first company organized for the exploitation of the coal beds in this region, and the construction of a railway running through the carboniferous region north to Concepcion. This was done with British capital, the Chilean government giving a guarantee for interest on the amount invested. It was only necessary to fall back on the guarantee during the first few years. After this the undertaking has been self-supporting, and it is understood that the guarantee money has been refunded.

South of these mines lies the new center of Pilpico, with the most magnificent deposits of the whole region. This is followed by a carboniferous district, 18 km. in length, as far as Cullinco, as yet unexplored, and which will produce the largest supplies of the future. The new railway from Curanilahue to Los Alamos will open up this region and connect the entire district to the coast, at the port of Lebu.

The river, in its journey to the sea, passes the oldest colliery district in the province of Arauco—the Errazuriz Establishment (which is now owned by the Curanilahue Co.), the Victoria and the Millaneca companies. The development of the Lebu mines has been sorely hampered, owing to the difficulties of the port, or rather to the lack of a proper port, as the formidable sand bar keeps everything over 200 tons outside in the open roadstead. The new railway from Los Sauces to Lebu via Canette will bring to the port of Lebu the coals of Curanilahue (which at present go by rail to Talcahuano), those of the new region between Curanilahue and Los Alamos, as well as those of the Lebu mines. It will therefore create a coal shipping center.

The Southern Railway Construction Co., which has been unable to complete the railway owing to the lack of sufficient capital and certain unforeseen difficulties, will no doubt eventually be bought out by the Chilean government and the work concluded, together with the necessary harbor works at Lebu. This railway will eventually be the main artery from Argentina to the Pacific, through the pass of Longuimay.

North of the Bay of Arauco there are found small coal deposits at Penco, in the Bays of Coliumo and Talcahuano, where the mines of Cerro Verde, El Rosal and Lirquen, about 2 miles from Penco, are being exploited. The coal from these mines is different in character from the others, being of a soft nature, and producing a coke that crumbles easily.

There are other lignite mines in the extreme south of Patagonia, within easy distance of the Port of Punta Arenas. The bed which is at present being exploited is 6 ft. thick and of an inferior quality. A local railway brings the coal to port.

According to data and statistics published in 1910, and the analysis published in the "Boletin de Geografiay Minas" in 1913, in the mines of Cerro Verdo, Lirquen and Rosal, in the region of Talcahuano, the heat content varies between 5764 and 6351 calories. The coals of Valdivia in the Region of Millahuillan belong to the same class. In the tests made by the State Railway Department these coals prove to be 25 per cent. inferior to the coals of Lota, Coronel and Arauco.

In the regions of Lota, Coronel, Collico, Curanilahue, Pilpico, Los Alamos, Cullinco, Lebu and Loreto, in Magallenes, the heat content varies between 7404 and 5156 calories. All these coals produce a compact coke, but which, owing to its chemical composition, is unsuitable for smelting purposes.

Owing to the war, the gas companies, which were previously dependent upon Australian coal, have been thrown back on Chilean material. The Santiago Gas Co. is modernizing its plant under the direction of a technical expert, who states that from experiments made on an extensive scale the Coronal coal gives the best results—results which compare favorably with those of the best Australian coal in quality and quantity of gas. The inferiority of Chilean coke rests principally in its friability, as its other properties compare favorably with the gas-cokes obtained from foreign coals.

The gross production in 1914 was 1,086,946 tons, the net amount sold being 944,829 tons. In 1915, which was also slightly below the average of the previous five years, the total production was 1,171,564 tons, or 1,050,874 tons sold. In 1914 and a part of 1915, with the nitrate and shipping trades practically at a standstill, the mines were obliged to reduce their output, but when trade was again opened, the collieries entered upon a period of unprecedented activity.

In analyzing the comparative outputs of the manual labor, one is struck with the low average production per operative employed in the Chilean mines, compared with that of other countries, especially Great Britain and the United States. This is due to a variety of causes, such as the difference in the thickness of the beds, the notably capricious nature of the deposits, and the conservatism of the owners, who prefer to drag along with manual labor, instead of introducing labor-saving machinery.

The comparative annual production per operative employed is given as follows: The United States, soft coal, 550 tons, anthracite, 380 tons; Great Britain, 280, Germany, 250; France, 200; Chile, 153; Belgium, 150.

The calorific value of coal is obtained by burning it in a calorimeter. At the same time the temperature of the burning coal can be determined by means of an electric thermometer. A fine high resistance wire is inserted in the combustion chamber of the calorimeter; the resistance of this wire is determined at the beginning of the test and during combustion. There is a definite relation between temperature and resistance and by this method the greatest temperature possible from a given coal can be determined.

Who's Who In Coal Mining

William Leckie

When we conjure up the vision of Colonel William Leckie, as we have seen and known him, he "comes up smiling." Cheerfulness, they say, is a religion with the Colonel, for he has read and mastered the Gospel of the Grin. Have it your own way. All we know is that the Colonel has a heart as warm as his smile is genial, that the bewitching curve of his facial muscles is an outward and visible sign of his inward and invisible heart's warmth—a warmth as genial as that generated by the product of his coal mines.

Colonel Leckie's good will is exhibited not only to his friends and to strangers, but to the hundreds who are in his employ. He not only feels kindly toward them, but serves them faithfully as their employer, providing

COLONEL WILLIAM LECKIE

liberally for their comfort and welfare. Probably this is because this successful Scot has been "through the mill," for he has not always been a coal operator.

Time was when he worked in the mines himself, not only in this but in the old country, and hard work it was, for his parents needed his labors, seeing that he was the oldest of 14 children. His parents were Samuel and Kate McClelland Leckie. He was born on the Smith farm, in Ayrshire, Scotland, near the birthplace of Scotland's poet, Robert Burns. It was not a very cheerful prospect when, as a lad, he went to the mines. Can it be that his life-long smile was incubated then amid those none too favorable surroundings? We can only wonder. The Colonel is not a man to dilate on his troubles or his hardships other than genially. Later he helped on the farm, and until he was of age part of his working time was spent on the surface and part in the mines—an amphibious existence not uncommon among the mining population.

When he was of age he came to the United States, settling in Shenandoah, Schuylkill County, Pennsylvania, whither his father followed him six months later.

William Leckie's first work in the mines in Pennsylvania was as repairman. Inspired by an ambition to equip himself for greater usefulness in life, young Leckie at the age of twenty-three entered Dickinson Seminary, at Williamsport, remaining there for two years and a half, seizing every opportunity to improve himself mentally and yet at the same time participating in all the activities of the institution where he was a student. He had as a very young man in Scotland been regarded as one of that country's best athletes. He demonstrated the same prowess as a student at Dickinson, and it goes without saying that he was a general favorite among the student body.

Soon after leaving college William Leckie was united in marriage to Miss Annie M. Kalb, daughter of the Rev. F. H. Kalb, a Presbyterian minister of Shenandoah, and to that happy union six children were born—Jean E., Nellie K., Andrew F., William S., Douglas E. and Miriam G. Leckie.

Possessed of an excellent education, William Leckie became successively fireboss for the Philadelphia & Reading Coal and Iron Co., inside foreman for the Buck Mountain Coal Co., near Delano, Penn., district superintendent of the Lehigh & Wilkes-Barre Coal Co., and finally general superintendent of the Lehigh Valley Coal Co.'s York Farm and Blackwood collieries, a position fraught with much responsibility.

His ability as a mining executive being widely recognized, William Leckie in 1894 was appointed general superintendent of the Aronfield Coal and Coke Co., near South Fork, Penn., and two years later he became general manager of the Loyal Hanna Coal and Coke Company.

Coming to West Virginia in 1901 as general superintendent of the Pocahontas Collieries Co., which opened up the famous Pocahontas coal fields, Colonel Leckie had a direct and responsible part in developing the properties of the Pocahontas mines, which eventually were acquired by the Pocahontas Consolidated Collieries Co. For six years William Leckie remained with this company. A man of sound judgment, William Leckie was also a man with a vision, though far from visionary, and he foresaw the great mineral possibilities of southern West Virginia. As a result he finally, in 1907, started in business for himself. Just how successful he has been is best attested to by the fact that he is now president and general manager of the following companies: West Virginia Pocahontas Coal Co., Lathrop and Panther Coal companies, Leckie Collieries Co., Leckie Fire Creek Coal Co. and the Douglas Coal Co. The general offices of all of the Leckie companies are at Welch, W. Va., where Colonel Leckie resides. In addition to his numerous coal holdings, Mr. Leckie is president of the Pond Creek Coal and Land Co. and of the First National Bank of Anawalt, as well as a director or stockholder in other business concerns.

Colonel Leckie's kindness to his employees is proverbial. Reference has already been made in *Coal Age* to his thoughtfulness of the mental, physical and spiritual welfare of those who are connected with his plants, but too much stress cannot be laid on the fact that he has sought to make the surroundings of the miners such that they would be happy and contented.

Though a native of Scotland, William Leckie esteems it a privilege to have become an American citizen, marrying an American wife and bringing up an American family who cherish American ideals.

Senate Investigating Committee Gathers Testimony on Hard Coal Situation

William Wilhelm, an attorney of Pottsville, Penn., in his testimony before the Senate Committee on Manufactures, which is continuing its investigation of the coal situation, ascribed the following reasons for the shortage of anthracite coal:

1. Refusal of operators to lease or to ship culm banks.
2. Refusal to allow the equipping of collieries to mine some of the very best deposits of coal—those which can be easily won.
3. Failure to join in the campaign for a larger production of coal.
4. Penalizing the brains of the willing workers.
5. Intemperance growing out of the fact that the breweries control the political situation in the anthracite fields.
6. Poor housing conditions.
7. Corporate landlords not opening mines themselves.
8. Excessive royalties.
9. Excessive tolls.

He cited the Girard estate as the best example of the payment of excessive royalties. He stated that the estate is getting as high as $1.40 a ton on prepared sizes of Locust Mountain coal. He says the trustees of the estate are taking the wealth of Schuylkill County and planting it in Philadelphia at the rate of millions a year. This led Senator Vardaman to state that "with the authority vested in the Federal officials, there is no reason why they should not have forced a change."

Mr. Wilhelm was particularly severe in his criticism of the breweries, on whom he fastened much of the blame for shortage in anthracite production. He declared that, in normal times, most of the stockholders in the big anthracite-producing companies live out of the country and that the business is run so as to squeeze out every possible dollar of profit. Coal is held in the ground, he declared, to keep it off the market. On being questioned, however, he afterward was forced to admit that there was no shortage of anthracite, except during strikes, until November, 1917.

William Griffith, of West Pittston, Penn., a mining engineer and geologist, told the committee that anthracite has reached the peak of production. He expressed the opinion that the Fuel Administration should have arranged a secondary grade of anthracite coal which could have been sold at a lower price. He said the clean coal regulation was wrong to the extent that it forced the grinding down of small sizes so they would come within the regulations in regard to impurities. In order to supply the demand during the war, he asserted that posterity has been robbed by gouging the mines of the more easily mined coal. He took issue with statements to the effect that schools were poor and living conditions bad in the anthracite region. He declared it was one of the most prosperous sections in the entire United States. He explained in detail why anthracite operators could not extend their mining activities indefinitely.

Jonathan Day, the commissioner of public markets in New York City, was outspoken in his condemnation of the Fuel Administration and the fuel administrator of New York. He declared the municipal authorities had plans perfected to give the poor people cheaper coal. The refusal of Federal authorities to allow the carrying out of the plan has made it necessary for the poor of New York to pay $3,000,000 more for their coal this winter.

The committee was surprised when Delos W. Cooke, the fuel administrator for New York, followed on the stand and displayed the entire correspondence between himself and the mayor of New York, showing that they were in entire accord. Mr. Cooke declared there would be no anthracite shortage in New York this winter, and despite Mr. Day's assertion to the contrary, declared there would be plenty of peddler's coal for the poor. He declared that the great majority of the poor would not traverse the long distances between the projected coal piles to save five or ten cents a bucket on coal. He went into detail as to the steps which have been taken to prevent a recurrence of the shortage of last winter. Principal among these was the appointment of an official to have entire charge of ice-breaking operations. Despite the heavy recent movements to the lakes and to New England, he declared that the deliveries are only 350,000 tons behind on New York's quota.

Gary N. Gray, of Scranton, Penn., the general manager of the Wolf Creek Coal Co., who has been forty-three years in coal-mining activities, was another witness. For the last twenty years he has been washing culm. Despite vigorous questioning, members of the committee were unable to show by his testimony that the big operators were at fault in not having worked their culm banks. Many washeries, he asserted, are closing because they cannot afford to pay the increase in wages. The demand for culm is also slack, he believes, from the fact that he has a number of cars under demurrage.

F. C. Reese, auditor for the Pennsylvania highways department, stated that the labor shortage in the anthracite region was due more to poor living conditions than to the draft or for any other reason.

W. S. Tompkins wired the committee from Wilkes-Barre, asking it to ascertain if the gas being allowed to escape from anthracite mines cannot be conserved. The committee was advised that the best heat units are lost in this manner, but no one vouched the opinion that it is practicable to save this gas.

Holiday Affects Coal Production

The Thanksgiving holiday cut heavily into both bituminous and anthracite production. With the ending of the war the men do not feel the same responsibility, and the cases were many where absence from work extended from Wednesday noon until Monday morning, according to advices reaching Washington. Despite the series of circumstances which have interfered with anthracite production the feeling in Washington is that requirements for that fuel are going to be so nearly met that no hardship will result.

Planning for a Large Export of Coal

Out of the changes resulting from the war will come a new policy respecting the exportation of coal, officials here believe. It is regarded as probable that the Government will establish foreign coaling stations. Much, too, will depend on the policy along which the merchant marine is conducted. Heretofore there has been no empty tonnage leaving our shores but, it is expected, conditions will have changed a year from this time. The reduction in the amount of exports to Europe and the completion of a large number of new ships will make available bottoms for coal exports.

If the United States should become a heavy exporter of coal, important changes would be brought about in the use of coal by domestic industries in certain sections. The only coal which could be exported with profit would be the high-grade product. This would necessitate the universal use of low-grade coal by domestic industries, Government specialists believe.

Bush Resigns as Head of Priorities Division of Fuel Administration

D. D. Bush, of the Peabody Coal Co., of Chicago, who has been devoting his time to Government work since the war, has resigned as head of the Priorities Bureau of the Fuel Administration. Mr. Bush will return to the service of the Peabody Coal Co. On first coming to Washington, Mr. Bush served the committee on coal production of the Council of National Defense. Then he went with the Fuel Administration until drafted by the Bureau of Mines to assist in the administering of the explosives act. Some months ago he returned to the Fuel Administration to assist in priority matters.

The Priorities Bureau is to be continued for the present under the direction of H. E. Brennick. Coal operators are having considerable trouble in getting delivery on important supplies, and it is believed that the Fuel Administration can render further assistance in transportation matters.

German coal and coke allowed for exportation to Sweden during the month of September amounted to 133,100 tons, or 17,000 tons less than the month previous.

May Abolish Soft Coal Prices

Price and zone restrictions on bituminous coal probably will be abolished on Dec. 15, Dr. Garfield has announced. The work of the administration, except that pertaining to anthracite, will have been so nearly completed by Jan. 1 that only a nucleus of each bureau will be maintained. The statistical bureau of the Fuel Administration is to be taken over by the Geological Survey. The engineering bureau, the power bureau and the conservation bureau will be taken over by the Bureau of Mines.

French Coal Mines in Bad Shape

Eight months must elapse before any production of coal may be expected from the mines at Lens, France. It will require three years to restore them to normal operation. This is the opinion of the Fuel Administration's commission, which now is in Europe. The Commission has conferred in Paris with the French authorities in the hope that it could make some helpful suggestion.

Clay Products Industries Save Much Coal

At least 1,500,000 tons of coal was made available for other purposes during the first half of the current year by the restrictions placed upon the clay product industries. Had the restrictions remained in effect throughout the year, the saving would have been at a higher rate, as many plants chose to burn their entire allotment of fuel and then close down entirely.

Brief Washington Notes

All restrictions on the use of fuel by florists and by the manufacturers of window glass, clay products and cement have been removed. The restrictions on fuel for breweries will be continued.

A coal handling plant capable of handling 500 tons per hour is to be erected on the waterfront at New Orleans. A storage bin will be provided with a capacity of 25,000 tons. The plan has been laid before the Fuel Administrator.

All restrictions on the movement of coke to and from New England have been removed. To save cross-hauling and traffic that could be dispensed with, the Fuel Administration last May placed an embargo on shipments through New England gateways.

Adjustment of zones west of Pittsburgh is under consideration. Unexpected slackening of demand is adding materially to the surplus coal in those zones. It is believed, however, that considerable relief can be afforded by certain shifts of the zone lines.

No leniency with regard to the clean coal order may be expected because peace is in sight, the Fuel Administration announces. It is continuing to close down mines that do not properly prepare their coal. More than 100 mines have been ordered closed for that reason.

Storage of coal at Pittsburgh was allowed to begin immediately following the completion of deliveries for Lake shipments. In order to insure the supplies needed in the Northwest, it was necessary to limit all domestic and industrial storage in the Pittsburgh district to actual necessity.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Perhaps the best labor news is the account of the labor unrest in Silesia, a part of German Poland. It is certain, of course, that German coal will never invade United States markets, but if wages were to remain low in Germany and at the same time coal were cheap, there would be a possibility of an underselling of our market by goods made in Germany; or, if not in Germany, in other countries with German coal or in other countries with the coal of those countries, cheaply mined by reason of the fact that, modeled on Germany, the wage scale in those countries continued to be low. These considerations made increased wages in Germany desirable, and also shorter hours. At last that desirable consummation seems to have been reached.

The Silesian mine workers are quite largely Poles and Russians. Formerly there was a large admixture of Entente prisoners. The prisoners are leaving, as might be expected. The Poles, not daring to revolt, are not unwilling to strike—anything to make trouble for the government. And with the Russians the magic word "Svoboda," which is supposed to mean "freedom," but in effect usually means "idleness," has done its fateful work. Wages in Silesia seem to have risen like those in Russia and are vainly striving to overtake the cost of living.

The miners were getting recently 25 marks ($5.95) per day of nine hours. They demanded the same pay for only a six-hour day. When the owners acceded to that the workers then demanded 30 marks ($7.14) for six hours. The Polish workers are believed to seek a continuance of the trouble so that they can seize the mines and declare them the property of the unions. The strike, therefore, is partly genuine labor trouble, partly socialism and partly politics. But whatever it may be, it promises good to the workers of the United States. The wage inequality is now on its way to readjustment, in fact is already readjusted. When all is done, it is likely that the walls of autocracy having fallen, the wage waters will tend to a level regardless of national lines.

* * *

We now approach the new election of officers of the United Mine Workers of America. It would seem that John P. White, like a soldier laddie, should be allowed to return to his former office now that the forces of the Fuel Administration are being demobilized and now that John P. White has sent in his resignation to the fuel board. The election will be held on Dec. 10.

Frank J. Hayes is a candidate for reëlection, having received the vote of 739 locals. John H. Walker, of Danville, Ill., a man of more radical tendencies, was nominated by 225 locals. John Lewis, who has been vice-president and desires to succeed himself, has been nominated by 880 locals. Opposed to him is Tom Kennedy, of Hazelton, president of district No. 7. He has only 23 locals behind his nomination.

Owing to the fact that there is a majority of bituminous mine workers in the union, the offices now always go to bituminous men. There are no party lines about this matter and no really clannish feeling, but the bituminous miners like to have bituminous labor leaders to settle their difficulties, and the anthracite men would like to have anthracite leaders. The bituminous mine workers always gain the day, owing to their greater numbers.

William Green, the secretary of the United Mine Workers, also seeks reëlection. He is opposed by J. L. Sims, of Linton, Ind. The greater number of nominations received by the present incumbent of the office appears to foreshadow his election.

The operators of the anthracite region are trying their utmost to meet the difficulties of the hard-coal situation. The promise that anthracite miners will be speedily demobilized offers some relief, if only there are not too extensive celebrations on their homecoming. Those in France may be some time coming home, and perhaps those who have not seen active service will be allowed to take their places in the ranks without any great consumption of time for a well-merited jubilation. However, it will almost pass belief if Scranton, Wilkes-Barre and Pottsville are not the centers of some few days of festival making "when the boys come home."

* * *

With the termination of hostilities miners in West Virginia fields are not inclined to work quite as regularly as they did when special appeals were being made to them to furnish coal for war purposes. In some districts their leaders do not and have not encouraged increased production at any time.

Labor organizers are still active in the Fairmont region, although that field is pretty well organized by this time. One of the latest local unions formed was that at the No. 7 Jamison mine of the Jamison Coal Co. Two strikes of minor importance have occurred in the Fairmont region within the last ten days. One was at the mines of the Orr Coal Co., between Fairmont and Clarksburg, the miners walking out after a dispute with officials. About 60 men are employed by the company. The trouble was adjusted within 24 hours and the men returned to work. A strike of a similar kind at the Rock Island mine in Barbour County was adjusted without much loss of time after the miners had presented their demands. About 150 men are employed at this operation.

* * *

A miner, by the name of Nick Gurkovich, employed in the Zeigler mine, has what is claimed to be the state record for loading coal. This was 333 tons for a single pay period of two weeks' duration. This pay period was the last half of October. The average for the entire mine was 13.7 tons for each loader for every work day in that pay. This high tonnage is due to the fact that the "turn" has been abolished and the men get every car they can load.

* * *

The United Mine Workers of America against the Hartford, the Coronado, the Mammoth and Prairie Creek Coal companies, all operating in Arkansas, comes up in the United States Court of Appeals, Tuesday, Dec. 10. This is a case where the operating companies obtained a $600,000 judgment against the mine workers of Arkansas in the District Court at Fort Smith, Ark., for the alleged malicious destruction of mine property during a strike. It will be remembered that the strikers deliberately destroyed by fire and other means tipples and plants of the mining companies in Arkansas which were idle when the company refused to run the mine on a union basis.

* * *

A conference of miners of District 18, which includes the eastern Section of British Columbia and the Province of Alberta, will be held on Jan. 6. At this meeting problems relative to coal-mining operations within the limits of that section and the men's attitude toward the same will be exhaustively discussed.

Thomas Graham, superintendent of the Canadian Collieries (Dunsmuir) Ltd., states that influenza has severely handicapped him in maintaining the output of the several mining properties under his charge. He asserts that the number of men who have laid off work for periods of varying length during the past few weeks runs into the hundreds. It has been impossible, therefore, to keep production up to the maximum point during November.

EDITORIALS

An Accusation That Does Not Asperse

REBUKING our friends in the press is never a pleasant task, especially when the journal is so reputable and well conducted an organ as the New York *Evening Sun*. Yet something should be said as to the unfair comment it allowed its correspondent to make on J. B. Neale's testimony in Washington, and as to the heading it permitted a headline writer to put on the story. The headline runs, "Coal Barons Dictate Price; Admit They Kept Surplus Out of Market," and the news item runs as follows:

"Something of the methods used by the anthracite operators of the country to prevent surplus production of the product and thereby prevent decreases in prices was related to the Senate Sub-Committee on Manufactures today. J. B. Neale, Director of Anthracite Production for the Fuel Administration, and himself a millionaire anthracite producer, was on the stand. Answering questions of Senator Reed of Missouri, he contended that before the period of Government supervision anthracite operators were always able to meet the demands of the country.

"'But there never was a surplus of anthracite,' Senator Reed remarked. 'There never was a surplus put on the market,' Mr. Neale corrected. 'This was done in order to keep up the prices,' asserted Senator Reed. The witness did not deny this."

The implication is that when a surplus output exists the failure to sell coal at any price, high or low, which can be obtained evidences a criminal conspiracy against the public. But is this conclusion fair? Is it not a fact that most papers sell on the stands everywhere and always at two cents a copy—no more, no less? Is it not also a fact that the newspaper publishers aim to restrict the output so that there will not be a surplus? Could it not also be proved that owing to that imperfect balancing of supply and demand to which newspaper vending is always subjected there is often a surplus of copies of these papers? What is done with the papers thus in surplus? Are they sold to the public at any price they will bring? Not at all; the price is kept at two cents uncompromisingly, and if the papers are not sold the output is deliberately destroyed.

The larger anthracite operators do not follow the journalistic detractors of the coal industry in their ruthless destruction of such property as is unsalable at the determined price. What they cannot get a fair price for they store and sell as soon as they can. Some of the small operators sell below that fair price, for they desire to keep their men working and meet their overhead; and some perhaps can afford to sell a little under the market. Any newspaper could also afford to sell its overplus under its market rate of two cents. Some could uniformly sell for less. But none of them do so. No one has yet condemned them, and why should we? But let their correspondents be more truthfully considerate of the position of the operators, for their own is, if anything, less honorable. For this reason let them exercise a genial censorship over their pages. The right of a man to ask a fair price and to insist upon it should not be questioned. If the price is not fair, that is a horse of a different color, as the correspondent we have quoted at length should, and is, doubtless able to observe.

It is interesting to note how curiously the public holds to two contrary doctrines—that of the fair price and that of unrestricted competition. The people believe they are always entitled to the lower price, whichever that may be. If competition has for years beggared an industry—and history records the time when the anthracite industry was so beggared—nevertheless nothing higher than a "fair price" must ever be put on the coal. As soon as competition reasserts itself the price must be allowed to fall to the lowest of levels without any resort to storage. Either the fair price or the competitive price should be the price set on an article. Those who call for the lower of the two require that the industry shall go on half rations, or no rations much of the time, and content itself with merely a life-sustaining meal on those rare occasions when unbounded prosperity furnishes the opportunity.

Abjure the Word "Not"

A CARTOON entitled "Early at the Garden Gate Was Late Paying for Liberty Bonds," which appeared recently in the pages of this publication, was exhibited to a friend who at one time had been an advertising man. The story it told seemed perhaps a little involved, and a criticism of that feature was fully expected. But to him that fault did not appear so large as it did to others.

The cartoon seemed to him to be badly conceived because, as he expressed it, it was "negative." It showed someone doing what he ought not to do. Our critic would rather have had it exhibit the man doing something that he ought to do, that it might stimulate others to do likewise. The man in the office saying "Nothing doing," grated on our friend's advertising sense and training. "The reply you are seeking," he said, "is 'Yes' and not 'No,' so why show a man resisting your appeal? You oppose yourself by the very nature of your communication. You arouse the very impulses which you wish to combat. You say to the man whom you address that his ideas are repugnant to those you entertain, and you have him battling at once against your point of view. Get 'Yes' into the air he breathes. Make compliance the natural course, and the work is half done."

This man was only indirectly interested in the coal industry. It is to be hoped therefore that he had not read many of the editorials that have appeared in *Coal Age* and counted just how often the negative side was taken when the positive would have been more helpful

and uplifting. If we will, all of us—operators, managers or editors—can rip out the "nots" and by a little reconstruction of our sentences express the same ideas just as clearly and forcefully without them. Let us abjure that short and savage adverbial particle "not."

There is a positive way of doing most things. Let the negative way come as a little-used expedient, as something that surprises us and the world around us, and not as the regular order of life, as it is too often with all of us today.

Greater Efficiency or Lower Wages?

REALIZING that the United States is the home of the high wage and the short working day, and therefore is handicapped when it enters into competition with foreign countries, there never have been voices wanting in the country to plead for wage reductions and longer hours. Somehow we have kept going with bigger wages and a shorter day. The source of our success has been largely in the superior intelligence and progressiveness of higher-paid and less-fatigued labor.

In efficiency lies our national strength. We have always had it, and it is to be hoped we always will. It is partly due to the physical condition of our workers, the outcome of fair wages and good living conditions. It arises partly from the intellectual quality of our artisans, the result of our common school education and of the freedom of thought which we have encouraged. It comes also in part from the good will existing between the worker and the planner, between the enterprising followers and the still more enterprising leaders in industry.

It has its origin partly in the fact that our men are in a degree the natural selection from foreign countries, the most aggressive, most physically able, the most hardy that Europe has afforded. We have for years drained Europe of its energy. Was there a man who had force in his arm, original impulses in his brain and idealism in his soul, he tended to come where all these things would have wider play—in a new field where they were likely to be less confined. As the Westerner is larger in body, broader in mind and more widely visioned than the Easterner, so in a way have we of America seen our problems and met them somewhat more originally than the people of Europe.

In 1917 the British coal mines produced only 243 tons per person, despite all the prodding which came from patriotism and necessity. It is true there were probably quite a few women among those persons, and with all regard for the fair sex most of them are not equal to men in performing the tasks around the mines. Perhaps we are not justified, therefore, in comparing "persons," male and female, with mine workers who are all males.

With this proviso we pass to the question of what we, in the United States, are doing. That is hard to determine, but Dr. Garfield, judging by the progress during the months preceding the close of the war, figured we would produce in a single year 600,000,000 tons of bituminous coal and 100,000,000 tons of anthracite. The war being over, we may not reach these stupendous figures; but if we do, seeing we have 720,000 mine workers, the average output will be nearly 1000 tons per man. The tonnage produced by each miner will be therefore between three and four times as much as that of the British operative. We probably have a few advantages in the physical conditions of our mines, and doubtless we secure part of our tonnage by being, on the whole, more wasteful of our coal; but the difference in production is remarkable in view of the fact that the coal mines of the United States are as wasteful of labor as they are of coal. The lack of coördination in the average American mine is deplorable. Men are continually waiting for cars, and the use of mechanical aids could easily be extended if only the basis of pay were such as to furnish the desired incentive to the operator. With a fixed scale per ton of output, the operator has no incentive to provide every known mechanical aid to production or to furnish the operative with effectual support.

But even with things as they are, why fear the competition of the foreigner? and why reduce wages? The man who produces three or four tonnages is entitled to better wages than the man who produces one tonnage, and such a wage can be secured to him. The only fear that we might well have is that having this splendid manhood we spoil it by forgetting how it has been obtained; how, having been obtained, it has been bettered. Let us avoid souring the laboring man by scolding him and meditating a wage reduction. He has done well, is doing well, and is going to do well if those who are undertaking his ordering and directing will see him as he is and not magnify his shortcomings, of which he has less than any workingman in any other clime or country.

Sewer Pipe for Water Lines

A GOOD way in hilly country to supply water for boilers and compressed-air engine intercoolers is by impounding water in little branch runs and directing it toward a large reservoir by sewer-pipe lines run on an extremely easy slope, following the contour lines more or less closely.

As a rule, for lack of capacity, only a part of the run-off that comes from a storm can be impounded in the reservoirs at any mining plant. But the water that is caught and rendered available during a dry spell can all be so saved. The sewer pipes, therefore, need not be large. They should be of such size as to carry satisfactorily the dry-water flows of the streams that they tap—always presupposing that taking that flow and redirecting it does not violate any riparian rights.

It might be well to block these pipes when the water is not needed, so that when the water is high and muddy they will not function and so block up. When the water is low and therefore clean, the mouths of the pipes can be opened and full use of their capacity can be made. "Sewer" lines should always be made tight and properly laid with full joints. If water can escape from the pipe, it is sure to leave the silt behind it and cause trouble.

It is a strange thing how generally the mining profession believes the sewer pipe to be a device in which only sanitary engineers are interested. There are many places where sewer pipe can be laid with advantage, but unless they are well and truly laid they will occasion trouble. There is too great an inclination among municipal, as among mining engineers, to slight the problems presented by sewer-pipe laying.

On Your Work Their Health Depends

When hard coal was rationed, New York and Philadelphia were left to the last. As they were near the anthracite field, it was expected that it would be easy to rush coal to them at any time. But influenza and patriotic celebrations have reduced the output immensely, and these good cities with their men, women and children are now, and expect to be later, extremely short of fuel. They appeal to the miner to do his best to reduce their suffering as much as possible.

DISCUSSION BY READERS

Hindrances to Coal Production

Letter No. 7—Being the secretary of the coal production committee at our mine, I am in a position to know what is the chief hindrance here to the mining of coal today. Frequent reference has been made in *Coal Age* to the booze habit of coal miners, and this I believe to be the one great cause that prevents our mines from being worked to their full capacity.

While I do not believe that coal miners as a class are intemperate, it must be acknowledged that some of our best miners drink and continue to imbibe as long as their money lasts. The result is that they get drunk and, for days, are incapacitated for work. When, finally, they do return to the mine they are in such a sad condition as to be wholly unfit either for business of for social duties.

Let me say, here, that I feel proud of the record that has been made at our mine, notwithstanding the fact that the influenza almost knocked us out, three of our men dying and thirty being off at one time. I am glad to say, however, that we are now coming out from under the influence of this terrible malady. Our men are coming back to work, weak and pale, but eager to get busy again and anxious to do their best in helping to solve the great problems following the war.

The influenza epidemic was one of those unavoidable causes with which we must occasionally contend; but it is one that comes and goes and not like the booze habit, which comes and stays. Booze among miners is therefore a worse evil and more difficult to overcome.

The Shame of Dealing Liquor Over a Bar

Speaking of intemperance, it is a shame that any individual who wants to be classed as a man will stand behind a bar and sell booze to a coal miner who he knows will get drunk and be unfit for work the next day. The small profit that comes to the hotel man is no compensation for the harm done to the coal industry by making the man drunk.

Let us say that the bar makes a profit of $2 a day from a miner who spends $5 out of his income of $8 or $10 a day. The transaction not only means a loss to the man and to his family, amounting to $12 or $15 or more in his pay, but a loss to the Government of eight or ten tons of coal every day the miner is out of his place. It seems strange that this hindrance to the production of coal and loss both to the Government and the individual miner should be permitted for the small profit of $2 a day to the booze man.

One of our men who has been on a spree for three weeks at a time tells me that his system, plan or method —call it what you may—has been the following: He would go to the hotel early in the morning, drink as much as he felt he could get home with, and then buy an extra quart to take home, as landlords in our country are not allowed to sell liquor in bottles. At home, he would drink the other quart and the next morning would find him again at the hotel. He would go through the same performance, day after day, till all his money was gone, when he would sober up and return to his work in the mine.

Let me ask if there is a Hun who, fighting against our boys "Over There," has hurt our cause as much as the man who deals out booze to the coal miner? Has not the time come for us to question the patriotism of such a dealer? I regret to say that it has recently been my duty to report five of our men for being intoxicated from one to three weeks at a time.

But, the mining of coal is not the only industry that is hindered by the booze habit of its workers. All employers of men are handicapped by reason of the same cause. We have been fighting the Hun abroad, for the sake of democracy and to make the world a safer place for living, which is surely a grand purpose; but how about the "Hun" at home? Should we not be consistent and strive equally to make our camps, boroughs, cities, county, state and country also safe for living?

Osceola Mills, Penn. S. D. HAINLEY.

Reversing an Electric Motor

Letter No. 1—Referring to the inquiry and the reply to the same, which appeared in *Coal Age*, Nov. 7, p. 878, regarding the question of reversing an electric motor, permit me to offer the following suggestions with a view to eliciting further information:

As the inquiry does not state the cause of the reversal of the current in the circuit, or how it became known that the polarity had been reversed, it is difficult to say much by way of explanation of such a fact. It is possible to reverse the magnetism of a dynamo field by an accidental short circuit between the external leads of the machine and the circuit supplied by another machine.

Early Experiences in Electrical Practice

In earlier days when, because of the limitations of electric-power plants for street service use, alternating current could not be used to advantage for that purpose, and, it was necessary to transform the current by means of a small series-wound, direct-current dynamo equipped with a regulator. It frequently happened that this machine would become grounded on the circuit of another machine, causing a residual magnetism of the field pieces. The dynamo would then build up in the wrong direction; or, as we would say, "upside-down."

It seems strange to me that a machine, which I assume was compound-wound, should become entirely reversed. It is possible that the wiring in the power house had been altered and the positive wire changed to the negative terminal. In any event, however, the

circuit is said to have been reversed and the question is, What effect such reversal would have on the motor in the mine. As stated in the reply to this inquiry, the reversal of the current in the circuit would not reverse the motor, which would continue to rotate in the same direction as before.

Electric Motors Differ from Dynamos in Not Being Self-Excited

It may be remarked, here, that all commercial types of motors used in mines are equipped with electric magnetic fields, which are excited from the main circuit. For that reason, residual magnetism is not required to build up a magnetic field to be cut by the armature, as in a dynamo, which is self-excited.

The current flowing through the field winding of the motor, in the case in question, would at once set up a magnetism in the opposite direction to that produced before reversal of the main circuit took place. Then, as has been explained, the armature circuit being also reversed, the direction of rotation of the motor would remain unchanged.

To my mind, I can see no trouble that could have occurred, unless it was caused by an attempt to parallel the reversed machine with one operating in the usual direction. The only effect of the reversed current would be probable damage to the switchboard instruments, owing to the current passing through them in the opposite direction.

Camp Jackson, S. C. Electric Maintenance.

Iron vs. Wood Mine Cars

Letter No. 5—I have read with much interest the remarks of John T. Cox, on the question of the use of iron and wood cars in coal-mining practice, *Coal Age*, Oct. 24, p. 793. Perhaps, there is no better way to discuss the merits of the steel car, as compared with the wood car, than to take Mr. Cox's letter, conceding, of course, that he has had considerable experience in the operation of coal mines and gives, in his letter, the results of that experience. My own experience with the steel and wood mine cars differs from his, however.

In the first place, the question of low or high coal, in my opinion can have no bearing on the type of construction of a mine car. At least, it has never occurred to me that the thickness of the seam enters seriously into this question; and my experience has been gained in different mines where the thickness of the coal has varied from twenty inches to thirty feet.

Flexibility vs. Rigidity in Mine Cars

Again, speaking of the flexibility of the wooden car in contrast with the rigidity of the steel car, it seems to me that this question cannot be discussed in an intelligent way without knowing something of the design of the car or its construction. I may say, however, that the wood car has been much more liable to keep the track than the more rigid iron car. Often, while going around the mines, I have seen cars or trips derailed, and when inquiring as to the cause have been told that it was the new cars which were too stiff and rigid. My personal opinion is that new cars have been responsible more than once for such derailments owing to their rigidity. I make this statement to show, if possible, that rigidity in the construction of a mine car is of no particular advantage, but rather detrimental to the efficiency of the equipment.

Mr. Cox refers to the necessity of inspecting the wood car more frequently. Although believing that this is a debatable question, I still contend that mine cars, whether built of wood or steel, should be inspected with equal care and sent to the shop for any slight repairs whenever necessary. I may also state that the mine cars of most coal mines get far less attention than they should, by the men in charge of the mines.

The question of dust-proof cars is one of considerable importance in the soft or bituminous mines of the country. I will, therefore, not argue that point further than to say that wood cars can be made dust-proof as well as iron cars. Also, in regard to replacing derailed cars, I agree with Mr. Cox that it is easier to replace a rigid car on the track, in a thin vein, than to do the same with a loose, flexible car, whether it be built of wood or steel.

Conditions Affecting Choice of Material

The question of which kind of car will require the greatest amount of repair and attention is of the most importance, and should be one of the controlling factors in deciding the question of what material the mine cars should be constructed. The conditions that affect the choice and which should be considered, before one finally decides the matter, are the following: (1) Size and capacity of the car; (2) style of construction; (3) the conditions under which the car must operate; (4) the dip or pitch of the seam; (5) kind of haulage employed; (6) amount of water encountered in the workings and its corrosive effect. An experience of several years in the anthracite mines of Pennsylvania leads me to say that the steel car is not adapted to the mines of this field.

Allow me to cite a few instances, here, that have come under my personal observation, and give my reasons why steel or iron cars are not adaptable for use in *all* anthracite mines, at least.

Steel Cars in Anthracite Mines

As already stated, one of the items that must be considered is the capacity of the car. If the car is to carry say three tons of coal, which is frequently the case, the construction of the car must be considered. Such a car built of iron will be much heavier, in proportion to its capacity, than a wooden car of the same cubical contents. If the vein or seam has a dip of, say ten degrees, that item alone will be one of considerable importance, as a heavy car will be handled with some difficulty if the hauling is to be done by mules.

The effect of acid mine water on steel cars is of much importance. During the past fifteen or twenty years some of the large coal-mining companies operating in this field have experimented considerably with this portion of their equipment.

The Susquehanna Coal Co., having collieries at Nanticoke, Penn., purchased a large number of steel cars, for use in their Stearns shaft, and my impression, now, is that these cars did not fulfill expectations. My recollection is that the bumpers or frame were found to be the weakest part of the car. The design was, then, changed to that of part steel and part wood, the

frame or sills being of wood, while the body was of steel and was bolted to the wooden truck. Although this did not give wholly satisfactory results, it proved much better than the all steel car.

The coal-mining department of the Delaware, Lackawanna & Western Railroad Co., a few years ago, decided to try out some steel cars, at several of their collieries in the Lackawanna and Wyoming coal fields. The results, in nearly all of these cases, were unsatisfactory, however, particularly where the mine water was strongly charged with destructive acids, which was the case in many of the mines.

From my experience in the mines of the anthracite region, I very much favor the use of a wood mine car. The suggestion that steel mine cars are worth something for scrap must, in my opinion, be considered from more than one angle. I have a case in mind, now, where a trip of eight cars ran away on a plane and was badly wrecked. The cost of cleaning up this wreck and removing the damaged cars to the surface and the delay occasioned thereby convinced me that a steel mine car was a misfit in the coal mines of this valley.

Kingston, Penn. AJAX.

Letter No. 6—In connection with the interesting discussion regarding the relative advantages to be derived from the use of iron or wood cars, in coal mining practice, allow me to submit the following as showing the high regard that users of steel cars have for that type of equipment. It is my belief that facts speak louder than words that merely express an opinion.

At the Ehrenfeld No. 8 mine of the Pennsylvania Coal and Coke Corporation, in Cambria County, there are 700 mine cars in use today. These are built of "Armco" iron, and to say that the cars give satisfaction but half expresses the high regard in which they are held by every mine official about the plant. Speaking of their service in the mine, everyone uses the most flattering terms.

The mine foreman at the Cresson colliery, in reply to my question regarding the quality of these cars, exclaimed, "Good service? Fine service! I wish, to goodness, that all my cars were of that class."

In deciding on the type of mine car to be adopted when equipping a large mine, one must use every precaution; and this led me, before leaving the place, to seek out the assistant superintendent, whose views I knew were always expressed with great candor. In reply to my inquiry asking what he thought of the use of iron cars as compared with wood cars, in mining practice, he exclaimed, "They are the real thing, those cars."

To show the style of iron car in use at the Ehrenfeld mine, I am sending a photograph of a portion of a trip standing on the track at the mine entrance. These cars were manufactured by the American Rolling Mill Co., Middletown, Ohio. The illustration shows the general form or style of construction of the car used in the Ehrenfeld mine where the seam has an average thickness of only 42 in. The height of the car is reduced and its length increased to conform with the conditions in this seam. The car was built with flaring sides and an end gate and has a capacity of about 2 tons. I offer this as an interesting presentation in favor of the use of iron mine cars in coal mining.

———, Penn. PROGRESSIVE.

TRIP OF STEEL CARS, AT THE EHRENFELD MINE, WHICH IS WORKING A 42-IN. SEAM OF COAL

Justice to the Miner

Letter No. 8—The cry heard on every hand today is "cleaner coal and more of it." The man who descends into the bowels of the earth has had it put up to him squarely that he must strive for a greater production of coal. The public, which is not familiar with actual mining conditions, has not been slow to cast reflections on the miner because he does not come across with a certain tonnage every day. The miner is accused either of being intoxicated, a casual worker or even a "slacker."

At times it has even been intimated that mine officials were not making the efforts they should to increase the output at their mines.

The honest miner feels the injustice of these charges, and I want to say that we who work underground are just as patriotic as men who are employed in other industries. Unlike these men, however, we are working under conditions that at times render us helpless to do all that we would like to do.

Coal mining today cannot be compared with coal mining of a few years ago. The anthracite mines have been noted for their high coal. In some instances the seam would reach a height of 20 or 30 ft. Moreover, the coal was of such a nature that it did not require much more than ordinary skill and effort on the part of the miner to produce a large tonnage. In the early days of coal mining, work was almost wholly confined to these large seams, where men established a record that cannot be equalled in present-day mining. It is much to be regretted that these big coal seams were sought after and mined exclusively in former days, while the smaller seams were left to be mined now when the cry is "coal, and more coal." Had men been content to work the small seams as well as the larger seams, there would not be the difficulty of finding coal today sufficient to meet the demands.

Contrasting Conditions in High Anthracite Seams with Those in Low Coal

Contrast for a moment the work in a seam of coal 15 ft. high, and having little refuse, where miners have averaged from 30 to 100 cars to a single keg of powder. In such seams there was plenty of headroom on the roads, which required no brushing of the roof or lifting of the bottom in order for the cars to follow the men in their advance. The miner suffered no inconvenience in moving about in his room, where he could stand upright.

Compare this condition with work in a 3-ft. or a 5-ft. seam, having from 6 to 12 in. of refuse that must be separated from the coal before it is loaded. Under such conditions is it to be wondered at that a miner cannot get out more than five or seven cars to the keg of powder. Consider, also, that in order for the cars to follow the men it is necessary to brush the roof or lift bottom varying from 12 in. to 3 ft. in depth. When one considers these facts it is clear that the miner is working under different conditions today.

Man Power in Coal Mining, Today

Men who profited by mining the high seams in former days would today find themselves confronted with a different proposition. Not only are the difficulties of mining increased, but there is a different class of men to be handled in the mines; and the situation is made worse by the fact that the opportunities offered by other industries have drawn away many of the best miners, which has greatly reduced the capacity of our mines. The sooner something is done to conserve the man power in mining and to induce good miners to stick to their work in the mines the better it will be for all concerned.

In the anthracite field there are acres upon acres of small seams that are still to be worked. The question is, where can we get the men to work them? Men are loath to work in these seams because they want to do their bit and measure up to the men working in other seams under more favorable conditions. To do this means that they would have to exert themselves to such an extent that they would not hold out for long, and so they seek work requiring less labor.

What is needed today, in the opinion of good mining men, is better equipment and such as will be adapted to present mining conditions. Face coveyors are needed in low seams. The height of the car must be reduced a few inches. Electric or compressed-air motors must be installed and everything possible must be done to reduce the labor required in the mining of these low seams.

Deadwork Impedes a Miner's Daily Tonnage

Only a few weeks ago I watched with interest a district where 25 men were working single-handed. The first day they loaded 75 cars of coal, the second day 60 cars, the third day 55 cars, the fourth 50 cars, the fifth 63 cars, and the sixth and last day of the week 56 cars, making a total of 359 cars of coal loaded by 25 men in six days, which is an average of less than 2½ cars per man per day. The average, in this district, would be three cars per man per day, and the reason this was not realized in the case I mention was the fact that the men had to work lifting bottoms much of the time, in order to get the cars to the face of the coal where they were loaded. An average of three cars per man per day would have produced, in this mine, 450 cars a week, which shows a loss of 450 — 359 = 91 cars of coal, or practically 20 per cent.

Let me urge, in closing, that the introduction of mechanical devices to lessen labor and maintain a fair average tonnage per man per day will greatly increase the production and lower the cost. The first outlay would be the greatest; the cost of maintenance would be small as compared with lifting bottoms, laying track and cleaning the coal, as the miner would not then get the rock mixed in with his coal. To just the extent that operators give their attention to installing suitable mechanical devices will they realize better results in their mines.

L. R. Thomas, Section Foreman,
Edwardsville, Penn. Woodward Mine.

Perplexities of Mine Foremen

Letter No. 4—No doubt every mine foreman has troubles of his own; but is it not true that many foremen make much of their difficulties and perplexities? This thought suggested itself to me when reading the letter of a mine foreman, which appeared in *Coal Age*, Oct. 24, p. 793, and in which he described the difficulties growing out of a condition, in a miner's place, where the machineman had to leave a thin layer of coal at the bottom, in order to avoid striking a roll at the other end of the cut.

The simple manner in which the superintendent, later, adjusted the matter led me to think that if the mine foreman had exercised an equal amount of tact and had foreseen the trouble that would arise if the matter got out of his hands, he would have avoided the snare into which he fell.

A mine foreman must deal with all classes of men, many of whom are indifferent to the needs of our country. There are men who would sleep if their house was afire, and there are miners who, when patriotism is mentioned and their need of getting out more coal is urged, will cause a diversion, by some remark that starts the laugh so that, for a time, the getting out of coal and patriotism are forgotten. The mine foreman who is on his job is well acquainted with that kind of a chap, and loses no time in giving him a hint to get busy at once.

Difficult Problem Confronting Foremen

A machinerunner is told to waste no time in getting his machine going, as men are waiting for their coal to be cut. Does he give heed to this gentle reminder and proceed at once to hasten his work? No! Too often it happens that the machineman is independent, knowing that competent men are scarce and that his job is safe. The question arises, What is the mine foreman to do under such circumstances; can he induce or compel men to continue to work when they want to quit?

Let me illustrate: In our mine there is a full crew of haulers, timbermen, roadmen and miners, who enter the mine in the morning ready for a full eight-hour day. The coal digger or loader starts to load his car; the machinerunner gets busy cutting the coal in the miners' places and the work goes on for five or six hours when a loader is seen going home. You ask him why he is going out so early. His reply is that he has loaded all the coal cut in his place.

A little further up the entry you come across a machinerunner making his way out of the mine. In answer to your anxious inquiries, he informs you that he is "tired and played out." You suggest that he "rest a bit and come back," to which he replies that he has had "plenty for one day."

The next day diggers are waiting for their coal to be cut; everything moves slow in the mine and the day's run falls far short of the average. The foreman is perplexed; yes, "perplexed" does not express his mental condition. He is at a loss to know what he can do to get his men to work the full day.

Mine Foremen and the "Square Deal"

In the letter to which I have referred, mention was made of the impossibility of a mine foreman getting a "square deal;" but he is not the only one to whom that will apply. When the machinerunner will not cut the coal, it is the miner who fails to get a square deal and must lose his day's work. It would only be justice to charge the machinerunner with the miner's loss of time when that is due to the former's neglect or unwillingness to work his full day.

It seems to me that there is but one remedy to apply to regulate these conditions, and that is to place the coal mines under martial law or operate them after the manner that controls the building of our ships. Many mine foremen and superintendents would welcome the authority that would keep mine workers in their places and compel them to perform their whole duties. Imagine, for a moment, what would be the result if coal mines were operated today on the same plan as shipyards where the workers cannot choose the number of hours they shall work. What interest can men have in the country's needs when they work five, six or sometimes seven hours out of the twenty-four. This kind of slackerism is far too manifest in the various branches of coal mining and, in my opinion, it can only be overcome by martial control.

While on this subject, let me mention the difficulty that surrounds a mine foreman having charge of from 250 to 300 men, scarcely 8 per cent. of whom can speak the English language and, perhaps, 15 or 20 per cent. additional barely understand the instructions given them, while the remainder require to be guided finger and thumb, in order to insure their safety, from the time they enter the mine until they reach the surface again.

Two Classes of Foreign Miners

We can divide the foreign-speaking miners into two classes: First, there is the foreigner who has been in this country six or seven years and worked in the coal mines for the same period. He cannot understand what is said to him, particularly if he desires not to understand.

Second, there is the foreigner who has been in this country from 10 to 20 years, without learning to talk any English. Many of this class appear to be more susceptible to instruction and, yet, like those in the first class, it is easy for them to fail to understand when they wish.

In control of both of these classes, there is generally one or more of their kin who are cute and cunning in their methods. These understand full well what is required, and have it in their power to regulate the output of the mine often with greater skill than the foreman himself. Because of this ability such are able to lead others of their flock in any way they desire, which puts the output of the mine largely in their control and adds greatly to the foreman's difficulties.

Foreign Miners Should Learn English

My suggestion, in this regard, may seem drastic. It is that the foreigner should be given a reasonable time to learn sufficient English to understand the instructions given him in the mine and after that should be compelled to make his wants known in English. As far as practicable, the speaking of a foreign language underground should be forbidden. The children in the schools should be urged by their teachers to talk English to their parents and older brothers who work in the mine.

It is my belief that the failure to learn to understand and speak English after a reasonable time should exclude a foreigner from the mine. This seems all the more important when one considers the seeming failure of attempts to bring foreign miners to know and obey the mining laws and regulations. These have been printed in the various languages and distributed through the mines. But, when a foreigner is caught violating one of the rules or laws, he feigns not to have understood that he was doing anything wrong. Therefore, it would seem that the prohibition of the use of the foreign tongue, in coal mining, is necessary to insure the safe operation of the mine.

Perryopolis, Penn. R. W. Lightburn.

INQUIRIES OF GENERAL INTEREST

Centrifugal Mine Pumps

Kindly answer the following questions regarding centrifugal mine pumps: (1) Is there any advantage in having either the suction or discharge pipes larger than what is called for on a centrifugal pump, and would such a larger size of discharge pipe prove any disadvantage in the operation of the pump? (2) What is the effect of a greater or lesser head than that for which a centrifugal pump is designed? (3) Is a long suction, say 500 ft., any particular disadvantage?

Pittsburgh, Penn. SUPERINTENDENT.

1. In replying to this question, it is necessary to understand what is meant by the size of discharge pipe "called for." We assume that our correspondent has reference to the size of the discharge portal of the pump as calling for the size of discharge pipe required. If that is the case, he is wrong in assuming that the diameter of the discharge portal calls for an equal diameter of the discharge pipe. The fact is the size of a discharge portal of a centrifugal pump is always less than the required diameter of the discharge pipe. As has been explained in *Coal Age*, Vol. 7, p. 263, the ratio of the diameter of the discharge pipe to that of the portal is independent of the quantity of water discharged and varies directly as the fourth root of the discharge head against which the pump operates. A convenient rule, in practice, is to make the ratio of the diameter of the pipe to that of the portal equal to 4/9 of the fourth root of the head expressed in feet.

For example, assume a No. 9, double suction, volute pump discharging against a head of 256 ft. The number of the pump is commonly taken as equal to the diameter of the discharge portal expressed in inches. Thus, the diameter of the discharge portal of a No. 9 pump would be 9 in. In that case, the ratio of the diameter of the discharge pipe to that of the discharge portal is $4/9 \sqrt[4]{256} = 4/9 \times 4 = 16/9$, and the diameter of the discharge pipe is, therefore, $16/9 \times 9 = 16$ in.

These remarks are based on an assumed perfection in the design of a double-suction, volute pump in which the tip velocity of the revolving vane approaches more or less closely to the velocity head of the water in the volute space surrounding the vane. This velocity is very high as compared with that permissible in the discharge pipe. While the theoretical velocity for a head of 100 ft. is practically 80 ft. per sec. (4800 ft. per min.), the flow in the discharge pipe should not exceed 6 or 8 ft. per sec., in order to keep the losses due to friction at a minimum.

2. Where a double-suction, volute pump is operating chiefly against frictional resistance, and there are few sharp bends or other obstructions to the flow, it can be assumed that the quantity of water discharged will vary approximately with the square root of the head. This, however, is only a general statement, and the effect of an increased or decreased head must be determined, in any case, by the characteristic curve of the pump, as furnished by the manufacturer.

3. A great length of suction is always a disadvantage, owing to the increased frictional resistance, which adds greatly to the suction head and increases the total head under which the pump must operate.

Hoisting Shaft Problems

We have sunk a shaft 130 ft. in depth, measured from the surface to the bottom of the coal. Kindly state what size of coal pillar should be left for the proper protection of the shaft. The coal is 6 ft. thick. Also estimating on hoisting a total load of 4 tons, including the weight of the cage, car and coal, what horsepower of engine will be required for the work in this shaft?

Corning, Ohio. MINE ENGINEER.

Numerous rules are given for determining the diameter of the shaft pillar required for the protection of a shaft. Most of these are based only on the depth of the shaft. The rule giving the least value for the diameter of a circular pillar or side of a square pillar is that of Merivale, which makes this dimension (d), in yards, equal to 22 times the square root of the depth (D) of the shaft, in feet, divided by 300, giving in this case,

$$d = 22\sqrt{\frac{D}{300}} = 22\sqrt{\frac{130}{300}} = 14\tfrac{1}{2} \text{ yd. or } 43\tfrac{1}{2} \text{ ft.}$$

The rule giving the greatest value for the same dimension is that of Hughes, which requires 1 yd. for each yard of depth, making the value of the required dimension, in this case, 130 feet.

A rule that gives better and more uniform results makes the value of the required dimension (d) three times the square root of the product of the depth (D) of the shaft and the thickness (t) of the seam, all expressed in feet, giving in this case,

$$d = 3\sqrt{Dt} = 3\sqrt{130 \times 6} = \text{say } 84 \text{ ft.}$$

In calculating the horsepower required for any given hoist, it is customary to add one-third to the total load hoisted, to allow for friction, etc. This increased load is then multiplied by the speed of winding (ft. per min.) and the product divided by 33,000, which will give the effective horsepower. This result must then be divided by the efficiency of the engine, which may be estimated as 85 per cent. for an ordinary slide-valve, noncondensing engine.

Assuming, in this case, a speed of hoisting of, say 15 ft. per sec. (900 ft. per min.), gives for the required horse-power of the engine.

$$H = \frac{4/3(4 \times 2000)900}{0.85 \times 33{,}000} = 342+ \text{ hp.}$$

EXAMINATION QUESTIONS

Mine Examiners' Examination Springfield, Ill., 1918

(Selected Questions)

Ques.—What are the duties of a mine examiner?

Ans.—The coal-mining laws of Illinois (Sec. 21) specify the following: (1) To examine the underground workings of the mine within 8 hours of the time when the men enter for work, or less if required by the mine inspector. (2) The mine examiner must carry a safety lamp that is in good condition and a rod or bar for sounding the roof. (3) He must ascertain that the air current is traveling in its proper course and that a sufficient volume of air is in circulation. He must measure the air passing in the last crosscut of each pair of entries, or the last room of each division in a longwall mine, and elsewhere if necessary, and must make note of these measurements in a book kept for that purpose. (4) The examiner must inspect all places where men are required to pass to and fro or to work and make note of any dangerous roof or accumulation of gas or obstructions of any kind in the rooms or airways. He must examine the edges and all accessible parts of falls and old gobs and aircourses to see that they are clear of gas. (5) The examiner must mark on the walls of each place, not on the face of the coal, the date of his examination. (6) He must place a conspicuous danger signal at the entrance of each place found to be dangerous, and place at least two obstructions, not less than 20 ft. apart, across the roadway leading to a room or heading where gas has been found, one of which must be outside the last open crosscut. (7) He must make a daily record of each examination, in a book kept for that purpose, before permitting the men to enter the mine for work. (8) The mine examiner must take possession of all entrance checks of men whose working places he has found to be dangerous, and deliver these checks to the mine manager (foreman), whose duty it will be to hold back the men from proceeding to their work.

Ques.—When do you consider the quantity of air entering the downcast shaft sufficient for the ventilation of the workings?

Ans.—The quantity of air entering a mine must be sufficient to comply with the requirements of the mining law and satisfy the mine inspector of the district. In addition to this, the total circulation must be sufficient to supply the particular needs in each district of the mine and keep the working faces free from accumulations of gas, assuming that the main current has been divided and the air distributed in proportion to the needs in each section of the mine. The velocity of the air at each working face must be sufficient to dilute, render harmless and sweep away the gases that would otherwise accumulate there or in any void and abandoned places in the mine.

Ques.—What will be the rubbing surface in an airway 3000 yd. long, 6 ft. high and 12 ft. wide?

Ans.—The perimeter of this airway is $2(6 + 12) = 36$ ft. The rubbing surface is then found by multiplying this perimeter by the length of the airway, which gives, in this case $36 \times 3000 \times 3 = 324{,}000$ sq.ft.

Ques.—Name the gases found in the coal mines of this state.

Ans.—The mine gases commonly found in Illinois are the following: Methane or marsh gas (CH_4), carbon dioxide (CO_2), carbon monoxide (CO), besides the nitrogen and oxygen of the atmosphere. In addition to these, also, there are sometimes found small quantities of hydrogen sulphide (H_2S) and the hydrocarbon gases, olephiant gas (C_2H_4) and ethane (C_2H_6), together with traces of hydrogen (H_2).

Ques.—State how you would make an examination of a coal mine, as mine examiner.

Ans.—Having prepared and carefully examined the safety lamp to be used in making the examination, start in time to complete the work in a thorough manner before the men must enter the mine in the morning. Before going into the mine, however, ascertain that the fan is working properly in the usual manner. Then, proceed at once to the foot of the downcast shaft or the intake airway and observe whether the usual quantity of air is passing into the mine. Having reached the district in charge, enter and examine each working place in order, following the air current from place to place, making a special test for gas in each place and examining the roof and coal to ascertain that they are in a safe condition for work. In each place examined, mark the date on the wall, as evidence of your visit.

In this manner, proceed throughout the district, examining not only the working face in each room and heading; but, also, the edges of all falls and the accessible parts of abandoned workings. Having completed the rounds, make a full record of the examination in the book kept for that purpose, noting those places where danger of any kind has been found and explaining its nature. This must be done before permitting the men to enter the mine for work. Finally, the mine examiner must take from the board all checks belonging to miners whose places he has found unsafe for work, and deliver such checks to the mine manager who will not permit the men to enter until their places are made safe for work.

Correction

A typographical error appeared in the answer to the last examination question appearing in *Coal Age*, Oct. 31, p. 838. The last lines of the answer given should read, Assuming a stroke of 18 in., the piston speed being 600 ft. per min., this engine must run at a speed of $(600 \times 12) \div 18 = 400$ strokes per minute, or 200 r.p.m.

COAL AND COKE NEWS

Harrisburg, Penn.

Members of the draft boards declare that they had not received any information as to when the many thousands of miners will be returned from the army by the War Department to their pre-war positions. As to the miners being given the priority of discharge from service, the draft boards were inclined to believe that if the Government contemplates such a move they will receive notification. If all return to their former occupations it is expected that it will result in an additional 300,000 tons of coal being mined every month in the hard coal fields, and it is deemed possible that the majority will resume their former task, as at the present time mine workers are receiving the highest wages in the history of the industry.

The coal companies have already placed requisitions with the Federal and State employment bureaus showing the number of men needed to bring the coal production to the maximum set by the Fuel Administration.

An important conference will be held in this city during the next two weeks, which will be attended by representatives from both the anthracite and bituminous regions, to prepare to secure an appropriation from the legislature at the coming session to make the Susquehanna River navigable, so as to secure a better outlet for coal and at the same time to get lower freight rates.

One of the leaders of the movement is Major Gray, whose survey made a few years ago revealed that the Susquehanna can be made navigable at a cost much less than that New York expended for the barge canal that extends across New York state.

Uniontown, Penn.

Acceptance of coke at the point of shipment rather than at the point of destination, provided in the contracts for coke for the first half year of 1919, mark an entirely new departure in the relations of producers in the Connellsville region with their customers, the blast furnaces. The clause in virtually all the new contracts will make necessary an inspection of all coke at the yards here, and commencing the first of the year many blast-furnace coke inspectors are expected to be assigned permanently to the Connellsville region.

All contracts made for the first half quote the Government fixed price of $6, but contain provisions making them subject to future price rulings of the Fuel Administration. Should the Fuel Administration be discontinued during the period of the contract, the contracts will be terminated at the last prevailing price of the administration. Although there have been intimations that the Government will shortly relinquish its control of the bituminous coal industry, no such action is expected for the present in the coke industry, which is so closely related with the production of iron and steel.

Although influenza is still responsible in a large measure for the continued reduction of output in the Connellsville fuel field, comparison of last week's output with the high war-time record presents in a fair way what the war-time stimulus did toward increasing production. The production for the week ended Nov. 23 shows a net decrease of 225,663 tons of coal from the high record of Oct. 12.

How highly the region was geared up to top-notch efficiency under the war demand for fuel is just now being appreciated by fuel administration officials who directed the war-time organization. They believe that throughout the war-time campaign the workers, especially the Slovaks, had a keener appreciation of the importance of their work than they were given credit for. With the war ended there is everywhere a tendency to relax effort, and no program has yet been outlined again to speed up production. The region is gradually being stabilized to conform to new conditions, but there is now no indication of attaining the peak production of early October.

There is yet an acute situation in by-product coal, some of the plants served by this region accepting high sulphur coal from which the byproducts may be developed. The coke produced from this coal is of an inferior grade, which may be sold for domestic purposes. Consumers are accepting this inferior coal rather than be forced to close down their plants.

Charleston, W. Va.

An ample flow of cars into the Fairmont district has resulted in a material increase in the coal output of that region. The car supply is now being stabilized, as the service all during the week ending Nov. 23 demonstrated. The average run of cars in the district during the period mentioned was in the neighborhood of 1700 cars a day, although Saturday was not such a good day, late deliveries being in evidence. While most of the coal went to the east, there was promise of heavier western shipments, especially in view of the fact that the Ohio market for byproduct fuel had been opened up.

Labor shortage is still cutting the output of the Tug River and Pocahontas districts to the extent of 47,120 tons a week, the total loss from the last report being 61,000 tons. There has been a slight though not marked tonnage loss from car shortage—about 7000 tons. Weekly production is about 415,000 tons. Coke production has diminished somewhat, though not materially, being 49,000 tons.

The mines of the Logan mining district are showing up a little better than was the case early in November, the last report showing a total production of 207,912 tons as against 186,922 tons for the previous week. The production loss has been reduced from 70,000 to 52,000 tons a week.

No diminution in the demand for coal has been felt in the New River field. The smokeless coal from that district is still in heavy demand, most of it going to New England and tidewater points. Mines in the district experienced a little difficulty again during the week ending Nov. 23 in securing sufficient power for all requirements. Car supply was ample for all needs, although coal movement eastward was slower than usual owing to congestion at certain points.

A damper was put on production in the Kanawha region by an embargo which began Nov. 18. On Nov. 25 the ban was lifted and coal began flowing again. No district has had a more restricted field in which to sell its coal than the Kanawha district. In justice to the district it is believed the Fuel Administration will modify some of its zone regulations so as to permit Kanawha coal to find its natural outlet, the slight congestion in the district being due to the unduly rigorous zone restrictions.

Birmingham, Ala.

Coal production in Alabama and the Birmingham district is disappointing. For the week ending Nov. 16 only 329,190 tons were mined. There is need for labor in some sections of the Birmingham district, and it is expected that quite a number of men will be available when demobilization begins.

The coke production of the district is being held back to some extent by the lagging coal output. Work on 304 byproduct coke ovens in the Birmingham district, 154 at Fairfield, 120 new byproduct coke ovens at the plant of the Sloss-Sheffield Steel and Iron Co. in North Birmingham, and 30 ovens at the new byproduct coke ovens plant of the Birmingham Coke and Byproducts Co. is being rushed. Announcement is made that machinery, material and all appurtenances for these plants are being gathered for shipment here at an early date, due to the fact that they are more easily obtained now.

The following statement on the situation in the district was obtained from Judge H. C. Sellheimer, Federal manager of production: "Alabama coal interests are likely to permanently lose a good part of the trade they controlled prior to the war unless some means of increasing the output is found. When the Fuel Administration created the zone system last spring it took away a considerable portion of the territory supplied by this district and placed it in other zones. Tennessee and Kentucky mines were permitted to ship to the Tennessee Valley towns, and Illinois and western Kentucky to the Mississippi Valley. Birmingham district mines have been unable to supply even the restricted territory assigned it and will not be able to do so again until production is considerably increased."

Victoria, B. C.

The collieries of Vancouver Island during the month of October mined 46,933 tons, an increase of 14,238 tons over the results of the previous month. Despite the loss due to influenza, the production of the Island for October stands the third highest for any month of the year, being only 4099 tons less than the output for March, the record month for 1918, and 1374 tons less than April, which ranks next in order. The Canadian Collieries (D), Ltd., is first with a total of 74,366 tons for the Comox and Wellington collieries, while the Canadian Western Fuel Co. is second with a production of 59,219 tons for the Nanaimo colliery. All the collieries show an increase over the month of September, except the Jingle Pot and the Grant. The tonnages mined by the collieries in the Nicola-Princeton district for the month of October aggregated 15,299 tons, an increase of 468 tons over the September total.

Six sets of the Gibbs oxygen breathing apparatus have been installed by the Department of Mines of British Columbia at the Fernie mine rescue station. These are the first specimens of this apparatus to be introduced into Canada. The Gibbs apparatus was recommended to the Minister of Mines by the chief inspector of mines, George Wilkinson, after investigation, and the former immediately gave the instructions necessary for their purchase and use in this Province. It is practically assured that the Gibbs apparatus will supersede that with which the other mine-rescue stations of British Columbia are equipped as soon as possible. It was thought best to place the first sets received at Fernie because of the very gaseous condition of the mines of the Crow's Nest Pass Field. It is understood that the Canadian Western Fuel Co. has some of this equipment on order, so that it is probable that the Gibbs soon will be in common use in this part of the Canadian West. Following the lead of British Columbia the mine authorities of the Province of Alberta are installing the same apparatus at coal mining centers.

PENNSYLVANIA

Anthracite

Hazleton—The Worthington Pump and Machinery Co. has released several hundred munitions workers. Many of these are former mine workers, and they are seeking their old positions.

Upper Lehigh—The Upper Lehigh Coal Co. suspended operations for the past two weeks, while the machinery of its old breaker was being transferred to the new breaker building, just completed.

Tamaqua—A washery erected on the Gerber tract, near here, by the "City of New York," has not yielded that municipality the return expected. An estimated daily output of 15 cars has reached but five cars daily, and that after a long delay.

Sandy Run — Operations at the new breaker of the Upper Lehigh Coal Co. will start about Dec. 1, work on the plant having been completed. The output of the mine will be greatly increased when operations in the breaker begin.

Hazelton—The Lehigh Valley Coal Co. on Nov. 26 raised the cost of fuel sold to employees. They must now pay the $1.05 increase allowed the operators by the Fuel Administration, but even at that the scale of prices is about $1 a ton less than to the general public.

Wilkes-Barre—The Hudson Coal Co. is ready to run the culm bank of the No. 2 colliery through the washery. The larger sizes will be mixed with freshly mined coal and sold to the retail and foreign trade. The bank has been in existence for about 40 years and contains thousands of tons of marketable coal.

Scranton—Owing to illness, it is said that John T. Dempsey, President of District No. 1, U. M. W. of A., in the anthracite region, has relinquished the duties of his office and they are now being performed by John Yanis, of Plymouth, the vice-president of the district organization. From a reliable source it was learned that members of the executive board of the district, in a recent meeting at headquarters, agreed to this plan.

Hazleton—Lehigh coal field operators face the winter with an immense amount of "dead work" to do to reach the coal. The cream of the coal, easily reached through culm banks, strippings and robbing pillars, has been taken at many collieries, and new tunnels, etc., must be driven to get to portions of the beds hitherto untouched. The new work will entail expenditures that will cut heavily into the reserve funds permitted by the Government under the income tax provisions.

Mahanoy City — James Mathews, of Shenadoah, was defeated by Chris Golden of Shamokin, for the presidency of District No. 9, United Mine Workers, in the anthracite region. The result was announced at the convention held on Nov. 27. Other officers elected are: vice president, John Strambo, Mahanoy City; secretary-treasurer, John J. McAndrew, Locust Gap; International executive board member, John J. Matts; subdistrict executive board member, George Litwin, New Philadelphia.

Avondale—Officials of the Delaware, Lackawanna & Western R. R., Coal Department, say that the destruction of the Avondale washery, on Nov. 28, will not seriously affect production at the Avondale colliery, as the machinery can be placed in position to resume operations immediately. None of the men employed in the washery will be thrown out of employment, but will be put to work readjusting the machinery and rebuilding the plant. For a time it was feared that the breaker would burn, fire breaking out on one side of the structure several times. This breaker was burned to the ground on Sept. 6, 1869, smothering to death 108 miners, who were at work. This was one of the largest disasters in the history of anthracite coal mining.

Bituminous

Washington—The McClane Mining Co. has contracted with the Roberts & Schaefer Co. for the installation of a Marcus picking table screen, to be installed at their tipple at Rich Hill Mine No. 1.

Pittsburgh—The United Coal Corporation has contracted with the Roberts & Schaefer Co. for the installation of a barge loading conveyor to be installed in the tipple at the Ella mine.

Johnstown—On account of the increased number of influenza cases in the soft-coal region of Cambria County, the fuel administration has ordered all saloons closed in a chain of mining towns from Gallitzin to Portage.

Washington—R. C. Masten, of Pittsburgh, president of the Masten Coal Co., has purchased 860 acres of coal for $450,000, according to information received here. The coal is located on the land of Owen Murphy, Donegal township, ten miles west of this place.

Homer City—A bathhouse has been erected here by the Homer City Coal Co., for the use of its employees. The structure is well equipped. Separate lockers for the clothing of the men and special equipment for drying and airing clothes, as well as showers with hot and cold water, are features of the building.

Huntingdon—A mine squeeze which occurred recently in the mine of Adam J. Black, at Broad Top City, was the greatest and most destructive in the history of the district. It happened in Cook Mine No. 3, and besides throwing 110 miners out of employment, the loss to Black is estimated at $35,000. There were 57 mine cars, 100 tons of iron, equipment and miners' tools inclosed by the squeeze.

WEST VIRGINIA

Logan—With all equipment in place and with a new tipple completed, the No. 2 mine of the Maher-Purseglove Mining Co., at Chauncey, has been put in commission.

Beckley—The Mead-Tolliver Coal Co. is about ready to begin operations at its new "Thistle" mine, battery haulage hotors having been received within the last few days, this virtually completing the equipment for the mine.

Orange—In the near future the Orange Gas Coal Co. will begin the mining and shipping of coal from its new mine in the Henshaw seam, at Orange, in the Coal River section. A. E. Moore is the general manager of the company.

KENTUCKY

Toler—The Roberts & Schaefer Co. has installed a Marcus picking table screen in the Bailey Coal Co. tipple.

Maysville—The Dodson Coal Co.'s elevator was destroyed by fire on Nov. 23, with a loss of about $38,000, on which there was only small insurance.

ALABAMA

Birmingham—A. H. Carpenter has been appointed assistant to Production Manager H. C. Selheimer, of the Fuel Administration in Alabama, and will devote his attention to the coke industry, endeavoring to bring about an increased yield and also an improvement in the quality of coke produced. As a result of demoralized conditions in coal mining, coke production has been badly hampered by the lack of the necessary coal for charging the ovens and also a shortage of labor. This situation is showing improvement and the output of coke is gaining slowly. The Brookside-Pratt Mining Co. has rehabilitated the battery of beehive ovens at the Murray Mine, near Blossburg, Ala., which has been idle for a number of years and will begin producing coke for the trade in the near future. There are 100 of these ovens. There is a shortage in the supply of both furnace and foundry coke. The New Castle Coal Co. is shipping about 2500 tons per month to the smelting interests in northern Mexico.

ILLINOIS

Edwardsville—The Beck-White Coal Co. has closed down its mine here and is removing the equipment.

Mt. Olive—The coal mines of this vicinity, after being closed several days on account of influenza, have reopened.

Springfield—It is estimated that the tonnage of Illinois coal in the past 30 days has been cut 50 per cent. on account of the influenza epidemic and the peace celebrations. The normal monthly supply of 4,500,000 tons will be reduced to about 2,000,000 tons for November.

Springfield—Miners of Springfield and vicinity have started a movement for the erection of a permanent home in this city. Under the present system the different locals meet in various parts of the city. Preliminary plans were made at a meeting of presidents and secretaries of the locals at the courthouse.

Springfield—The various locals of the United Mine Workers are considering the permanent leasing of a hall for the meeting place of these organizations. At the present time there is no regular and permanent meeting place and the locals meet all over the city. Better results can be expected if the locals meet in one place, it is believed.

Marion—An interesting event in the past week was the breaking through from the Peabody No. 3 mine into the workings of the old Carterville district mine, which was abandoned on account of fire about four years ago. The old workings were found in good condition, with very little water and gas. The gas was the cause of the worry when the connection was made.

Murphysboro—The State Miners' Examining Board, of which William Hall, of Springfield, is president, held examinations here and in Duquoin on Dec. 2, and on Dec. 3 and 4 in Herrin. Other examinations announced are Dec. 5 and 6, West Frankfort; Dec. 7, Harrisburg; Dec. 9, Christopher; Dec. 11, Belleville; Dec. 12, Collinsville; Dec. 16, Danville; Dec. 17, La Salle; Dec. 18, Peoria.

Carlinville—An advertisement of a sale of alien property in this vicinity has aroused considerable local interest. The sale involves about 30,000 acres of coal rights owned by the Ely Coal Co., of Girard, which has been seized by A. Mitchell Palmer, Alien Property Custodian, as alien-owned coal lands and will be sold at public sale to "100 per cent. Americans." It is expected that there will be some spirited bidding, as a large acreage of coal rights in one body in the state is uncommon and hard to purchase.

Foreign News

St. John's, Newfoundland.—The Reid Newfoundland Co. is developing along scientific lines a highly promising coal seam recently discovered near Codroy, on the west coast of the island, within one mile of the railroad and accessible to tidewater. It has been found to be 11 ft. in width and it is believed to be an extension of the coal deposits of Cape Breton. Should its development prove commercially profitable, it is estimated that within 18 months it should be possible to obtain from this mine the 200,000 tons of coal now annually imported to Newfoundland from Nova Scotia. Important iron ore discoveries are also stated to have been made by the company, but no official announcement respecting them has been made.

Personals

J. Frank Hay, purchasing agent for the Buck Run Coal Co., Minersville, Penn., has resigned to accept a similar position with a railway company at Pottsville.

Joseph E. McGowan has been elected a member of the board of directors of the Maryland Coal Co., of Maryland, and the Maryland Coal Co., of West Virginia, succeeding Howard S. Dickson, deceased.

Thomas Kelshaw, inspector for the Coxe estate in the Hazleton region, has resigned to enter the employ of the Girard Water Co., as superintendent of its coal and water business in Schuylkill County. **W. E. Millington**, formerly with the Girard estate, Pottsville, Penn., will succeed Mr. Kelshaw.

Dwight P. Robinson, a former partner of Stone & Webster, in charge of their construction and engineering business, has opened offices in New York under the name of Dwight P. Robinson & Co., Inc., constructing and consulting engineers. Associated with him will be **R. M. Henderson**, in charge of construction; **C. W. E. Clarke**, mechanical engineer; **R. A. Philip** and **D. L. Galusha**, electrical engineers, and **M. E. Thomas**, structural engineer.

Lieut.-Col. L. G. McCrum, who in private life is general manager of W. H. Bradford & Co., Inc., with mines in Somerset, Cambria and Huntingdon counties, Pennsylvania, and president of the Victor Coal Mining Co., of Somerset, Penn., has met with considerable success since he assumed the general managership of the Government Arsenal at Rock Island. In fact, so free from labor trouble was the arsenal, and so great a spirit of coöperation and loyalty had Colonel McCrum succeeded in inculcating among the thousands of employees, that his results have attracted the attention of official Washington. Colonel McCrum will resume his duties with the Bradford company when his work with the Government comes to an end.

Obituary

F. N. Day, of Hazleton, Penn., secretary of Pardee & Co. for many years, died recently of ailments incident to old age.

John Pugh, of Kingston, Penn., aged 67, one of best known mining men in the anthracite coal region, died on Nov. 26, at his home, following a prolonged illness. He was a man well versed in sinking mine shafts and his operations extend throughout the anthracite and soft coal fields of Pennsylvania and Virginia. His widow and three sons survive.

Evan D. John, director of the Illinois Department of Mines and Minerals, died at St. John's Hospital, Springfield, Ill., Thanksgiving morning, at 6:45 o'clock, after an illness of five weeks due to a complication of diseases. Mr. John was 57 years of age and had been prominent in state mine work for a number of years. He served several terms as mine inspector under Governors Tanner and Deneen, and was a member of the state mining board in 1910, serving for a time as its president. After the consolidation of various state bureaus under the direction of Governor Lowden, Mr. John was named Director of the State Department of Mines and Minerals. In this capacity he had shown excellent judgment and ability, especially during the period of the war, when the mines of the state were taxed to their limit in producing coal. Mr. John was 57 years of age. His home was at Carbondale, Ill. He is survived by his widow, one son and three daughters.

Smoke Consumer. A. Habig, Montreal, Quebec, Can., 1,278,639. Sept. 10, 1918. Filed Oct. 26, 1915. Serial No. 58,007.

Smoke Consumer. R. J. Johnson, Lake Benton, Minn., 1,278,937. Sept. 17, 1918. Filed May 10, 1917. Serial No. 167,770.

Safety Device for Mine Cages. L. Pichler, Fort Wayne, Ind., 1,278,742. Sept. 10, 1918. Filed Jan. 10, 1918. Serial No. 211,207.

Coupling for Mining Cars. H. J. Williams, Nanticoke, Penn., 1,278,541. Sept. 10, 1918. Filed May 4, 1918. Serial No. 232,534.

Smoke Consuming Apparatus. I. Therrien, Quebec, Can., 1,279,939. Sept. 24, 1918. Filed Mar. 12, 1917. Serial No. 154,197.

Furnace Arch. J. S. Fulton, assignor to United Stokers Corporation, Chicago, Ill., 1,278,326. Sept. 10, 1918. Filed Oct. 31, 1917. Serial No. 199,577.

Furnace Structure. R. M. Spencer, assignor Columbus Heating and Ventilating Co., Columbus, Ohio, 1,278,777. Sept. 10, 1918. Filed Jan. 23, 1913. Serial No. 743,721.

Industrial News

Manchester, Ky.—The Horse Creek Coal Co. has filed notice of an increase in its capital to $24,000.

Columbus, Ohio—The Flint Ridge Coal Co. has increased its authorized capital from $1000 to $275,000.

Louisville, Ky.—The Harlan Coal Co. has filed notice of an increase in its capitalization from $200,000 to $250,000, to provide for proposed extension.

Youngstown, Ohio—The Youngstown Sheet and Tube Co. has completed arrangements for the construction of a large new coal-handling plant at its works.

Phillipsburg, Penn.—The Hindle Coal Co. has been incorporated with a capital of $20,000 to operate a general coal business. W. H. Hindle is the principle incorporator.

Sunbury, Penn.—The Shoop Coal Co. has been granted permission by the State Water Supply Commission to dredge coal from the Shamokin Creek in the vicinity of Sunbury.

Philadelphia, Penn.—The Holler Coal Co. has been incorporated with a capital of $20,000, to engage in general coal-mining operations. B. D. Jones is the principal incorporator.

Chicago, Ill.—The Chicago Pneumatic Tool Co. announces the appointment of L. C. Sprague as assistant secretary of the company, with headquarters at 52 Vanderbilt Ave., New York City.

Dover, N. H.—The Boston & Maine Railroad Co., Boston, Mass., has awarded a contract to the H. Wales Lines Co., 134 State Street, Meriden, Conn., for the erection of a new coaling station at its local properties.

Ashland, Ky.—The Lackey Mining Co., capital $12,000, has been incorporated by J. W. Kitchen, Sam Porter and R. D. Clere. Mr. Kitchen is an extensive lumber operator with large interests in Kentucky and Tennessee.

Webster, Penn.—The United Coal Co., First National Bank Building, Pittsburgh, has awarded a contract to Phiel & Miller, Wabash Building, Pittsburgh, for the construction of a new river coal tipple at its local properties.

Morton's Gap, Ky.—The Peerless Coal Mining Co. has been incorporated with a capital of $60,000 to develop coal properties in the Morton's Gap district. H. L. Browning, Cleve Medlock and William O'Bryant are the incorporators.

Charleston, W. Va.—The American Eagle Colliery Co. has been incorporated with a capital of $600,000 to engage in general coal-mining operations. V. L. Black, George S. Crouch and L. G. Summerfield are the principal incorporators.

Chicago, Ill.—The John A. Stewart Electric Co., John A. Stewart, president, formerly of Cincinnati, Ohio, has opened offices in Chicago at Room 1034, 208 S. La Salle St. The company will handle second-hand machinery, both electric and steam.

Clarksburg, W. Va.—The Gaston Coal Co. has been incorporated with a capital of $25,000 to engage in the development of coal properties in the vicinity of Clarksburg. James Cain, Elkins; and R. L. and H. L. Hart, Clarksburg, are the incorporators.

Scranton, Penn.—The Barton Coal Co., Scranton Life Insurance Building, is planning for the immediate erection of a new coal washer at its properties at Peckville, to have a capacity of 500 tons. The structure is estimated to cost $15,000.

Sandy Run, Penn.—M. S. Kemmerer & Co. have completed arrangements for the construction of a new one-story coal breaker at their local properties, estimated to cost $10,000. Frank B. Davenport, Coal Exchange Building, Wilkes-Barre, is engineer.

McKeesport, Penn.—The Firth Sterling Steel Co. has awarded a contract to Phiel & Miller, Wabash Building, Pittsburgh, for the construction of a large new coal-handling plant at its works, to cost, in connection with other improvements, approximately $200,000.

Charleston, W. Va.—The Charleston Coöperative Coal Co., recently incorporated with a capital of $96,000, is planning to commence work at an early date on the development of approximately 900 acres of coal properties in the Riverview section, to have a capacity of 100 tons daily. H. J. Ferimer, Catlettsburg, Ky., is president.

Fairmont, W. Va.—A ruling of the state fuel administration, recently issued, requires all retail coal and coke dealers to register with the county fuel committee on or before Dec. 10. Such registration, which will be made without charge, is to be a prerequisite to the transaction of any business, and each such retail dealer must register in each county in which he deals.

Wilmington, Del.—It was announced on Nov. 25 that the Pennsylvania R. R. has purchased ten acres of land adjoining the tract secured by them some time ago at Gordon Heights, for their proposed coal piers, which are to be moved from Greenwich Point. The lands purchased will enable the company to construct miles of tracks adjoining the piers and runs parallel with their present main line.

Wilkes-Barre, Penn.—Wilkes-Barre's coal land assessment will be 25 per cent. higher during the next three years. This was decided on Nov. 23, at a meeting of the board of assessors under the triennial assessment. The coal lands today are valued in the city at $15,000,000 and will be increased to almost $21,000,000. Under the old assessment anthracite taxable property brought $130,000 yearly in taxes to the city.

Bluefield, W. Va.—The King Coal Co., according to a well-substantiated report, became a part of the extensive interests of the Houston Coal Co., headed by T. E. Houston, of Cincinnati, on Dec. 1. The King Coal Co. includes what was formerly operated as the Tidewater Coal and Coke Co. While the consideration involved has not been made public, it is said to involve a large sum and the deal is said to be one of the largest and most important consummated in West Virginia in some time.

Cincinnati, Ohio—At a meeting of leading members of the coal trade, including prominent operators and dealers, held at the Hotel Sinton on Nov. 25, the situation in this section was declared to be satisfactory for the coming winter, although the amount of coal available for distribution was stated to be limited. The volume of fuel stored by domestic consumers is such that there will be little suffering should very severe weather come, it was stated. The labor situation at the mines was discussed, as was the outlook for the export trade.

Charleston, W. Va.—Changes have been made in the districts of several of the district mine inspectors by the State Department of Mines. James Golden, of the Ninth district, has been transferred to the Fourth district at Fairmont. H. L. Butler has been transferred from the Fourteenth district to the Thirteenth at Welch. R. L. Lambee goes from the Tenth to the Ninth district at Macdonald. L. B. Holliday has been transferred from the Thirteenth to the Sixth district at Charleston, and Eli Mason will hereafter have charge of the Tenth district, being transferred from the Fifth district.

Charleston, W. Va.—The Chesapeake & Ohio Ry. has cut down the daily quota of cars for each mining district receiving empties from its lines because of the reduction of production during a part of October, due principally to the influenza epidemic. Operators declare this is not fair because production would have been extremely large but for the epidemic. The road has promised, however, to see that mines have enough cars. The allotment reductions for empties measured in tons per day are as follows: Kanawha, from 42,570 to 26,650; New River, from 41,940 to 26,890; Coal River, from 16,400 to 9870; Guyan, from 67,930 to 41,340.

Washington, D. C.—At a meeting of the executive committee of the National Retail Coal Merchants Association, held here Nov. 11 and 12, a number of important matters were discussed. Cyrus Garnsey, Jr., assistant Federal Fuel Administrator, met with the committee and discussed freely many of the problems confronting the Administration and the retail dealers. The organization went on record as favoring 2000 lb. as the standard weight of a ton of coal, and the officers were authorized to secure legislation to that end. A resolution was adopted proposing the continuation of the Fuel Administration for the remainder of the coal year.

Columbus, Ohio—War prosperity, together with careful management, has resulted in the lifting of the receivership of the Sunday Creek Coal Co., of Columbus. The receivership was brought about more than three years ago by creditors, and John H. Winder was named as receiver. Previous to that time an equity in the company had been acquired by John S. Jones. During the receivership all of the claims were paid off, and Mr. Jones acquired practically all of the outstanding securities, including stocks and bonds. Attorney Barton Griffith has been president, but he is expected to resign, and Mr. Winder will be named to that position.

Philadelphia, Penn. — The Greensburg Coal and Coke Co., Commercial Trust Building, has received a letter from the commanding general of the Eastern Department Headquarters of the United States Army, expressing deep appreciation of the hearty coöperation rendered by the company in the recent campaign to secure candidates for the Infantry Central Officers' Training School, at Camp Fremont, California. The Greensburg Coal and Coke Co. furnished office facilities and clerical assistance to Capt. H. G. Vawter, examining officer from the Eastern Headquarters, and rendered a service that was deemed of great value to the War Department.

Morgantown, W. Va.—What may be termed the salvation of the Scott's Run operations, whose owners belong to what is known as the Scott's Run Operators' Association, is the decision of the Railroad Administration putting into effect a prorate between the Morgantown & Wheeling Ry., over which coal is transported to the connecting line—The Monongahela Ry.—and the latter line, relieving the operators of 40c. a ton on coal for a very short haul—a charge which threatened to drive the Scott's Run people out of business. Before the new rate becomes effective it will have to be approved by the circuit court, since the short-line railroad company is being operated by a receiver.

New York, N. Y.—The Exchange Bureau of the wholesale Coal Trade Association of New York, Inc., will be put into operation on Dec. 9, and the first list of offerings and requirements will be distributed the following day. But one change has been made in the rules, a summary of which has already been printed in *Coal Age*, (Vol. 14, No. 22, p. 1006), the price at which coal is offered will not be shown, it being decided by the Board of Directors that all matters other than the mere bringing together of the parties should be left to those directly interested. The Board of Directors also reached the conclusion that it will not be possible to extend the privileges of the Coal Exchange to retail dealers.

Toledo, Ohio—With the lake season almost over, lake shippers at this port are going over records to see just what the season had in store for them. On the whole the season was probably the most successful in the history of the lakes and a large tonnage was moved to the Northwest. The Hocking Valley docks up to Nov. 23 loaded 5,021,345 tons, which is almost 200,000 more tons than were loaded during the entire season of 1917. The docks loaded 100,487 tons during the week ending Nov. 23, compared with 125,798 tons the previous week. Officials of the Hocking Valley Railway said that there were approximately 1600 cars yet to be loaded on vessels. The Toledo & Ohio Central docks during the week ending Nov. 23 loaded 50,000 tons as compared with 135,000 tons the previous week, making a total of 2,174,028 tons.

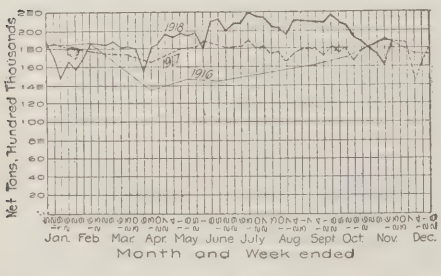
MARKET DEPARTMENT

Weekly Review

Opinion Divided as Regards Continuation of Federal Control of Soft Coal Industry—Strong Arguments for Returning Industry to Competitive Basis — Anthracite Situation Will Probably Right Itself by End of Year

SHALL the Federal Fuel Administration continue to exercise its control of the coal industry, or shall it wind up its affairs at once and permit the law of supply and demand to prevail, as in pre-war days? This, in essence, is the all-absorbing question now being discussed in coal-trade circles. Opinion is by no means unanimous. Operators who are mining high-grade bituminous coal are emphatic in their demands that the industry be returned to a competitive basis, while those mine owners who are not so favorably situated as regards the excellence of their product desire that the Administration function until its life expires with the signing of the peace treaty. Indications, however, point to an early relinquishment of control of the soft-coal industry by the Administration; and the stage is being set with this end in view.

When the country was at war, every step taken to encourage maximum production was a step in the right direction, and every restriction placed on distribution was so placed for a very definite reason. With the country at peace, however, most of these radical innovations are no longer necessary. Instead of quantity, the demand of the consumer is now for quality. The market is overstocked with soft coal, much of it of an inferior grade that can find no buyers. In the meantime the high-grade coals that consumers in certain zones would gladly purchase are being produced by mines in other sections of the country; and, unfortunately, many of these mines have been forced to curtail operations because the zoning laws prohibit them from shipping their product outside the established boundaries.



It is evident, therefore, that the Fuel Administration will go far toward stabilizing the coal industry and benefiting the consumer when it gives up control of bituminous coal. Inefficient mines, and mines producing poor coal, will then no longer be in position to market their product at prices which are beyond all reason, and high-grade coals will once more be enabled to sell in localities where a demand exists for them.

It can be stated as an axiom that whatever is true of soft coal is untrue of anthracite. This being the case, therefore, the continued control of the production and distribution of hard coal by the Fuel Administration would seem to be the most logical course to pursue in order to prevent profiteering. Anthracite is as scarce as bituminous is plentiful, though the shortage is confined chiefly to Pennsylvania, Delaware, New Jersey and New York—states that are quite near the source of supply.

The anthracite shortage in the localities named amounts to 626,776 tons, which is less than three average days' output of the mines. With augmentations to the labor forces from the ranks of those released from the army and discharged from munitions works and other war industries, it is expected that the deliveries of hard coal will be brought up to the allotments set by the authorities by the end of the year.

WEEKLY COAL PRODUCTION

The record-breaking steady decline in the production of bituminous coal, from the high point of over 13,000,000 tons a week, the last of September, to less than 10,000,000 tons, seven weeks later, came to an end the middle of November. In the week ended Nov. 23 production rose to nearly 11,000,000 tons, a gain of 12.5 per cent. The estimated production in the week of Nov. 23, 1918, was 10,931,000 tons, compared with 9,703,000 tons in the week of Nov. 14, and 11,187,000 tons, or 2.3 per cent. less than in the corresponding week

of 1917. The average daily output rose from 1,617,000 tons to 1,820,000 tons, but below the figure of 1,865,000 tons for the corresponding week of 1917. The total production of bituminous coal and lignite, including coal coked, Apr. 1 to Nov. 23, is estimated at nearly 400,000,000 net tons, a gain over the corresponding period of 1917 of 40,000,000 tons, or 11 per cent.

Reports of production and working time for the week of November 16 show for the first time this year loss of production because of no market comparable to the loss because of transportation disability. The transition in the comparatively short period of a few weeks from a condition of car shortage to one of car surplus is significant because indicative of the possibility of a reversal later with a return of unfavorable conditions. This condition has been brought about by the accumulation of stocks, made possible by the heavy shipments during the past four months, the possession of which has taken the keen edge off the industrial demand, and by the fair weather for this time of the year that, while favoring transportation, decreases the consumption of coal.

The production of anthracite in the week ended Nov. 23 is estimated at 1,778,000 net tons, an increase compared with the week of Nov. 16, of 373,000 tons, or nearly 27 per cent., but 263,00 tons, or 13 per cent., below the corresponding period in 1917. The total production of anthracite, Apr. 1 to date, is estimated at 65,358,000 net tons.

All districts except southwest Virginia shared in the increase in the week of Nov. 23 over the previous week, but all districts except Fairmont were below the corresponding week of 1917. The totals for the year to date for all districts are greater than the same period of 1917.

Coal dumped at Lake Erie ports, including vessel fuel, in the week ended Nov. 23 was 567,990 tons, a decrease of 71,500 tons compared with the week of Nov. 16. Nov. 23 marked the official closing of the lake season of 1918, and with nearly 28,000,000 tons of cargo coal dumped at lower lake ports set a new high record. Loading of coal at the mines for lake shipment ceased (except for small quantities of special-purpose coal) on Nov. 16, two weeks earlier than last year.

Shipments of bituminous coal to New England in the week ended Nov. 23 were 412,376 net tons, 1200 tons less than in the week of Nov. 16, but below the average per week from Apr. 1 to date of 569,729 tons. Under the recently revised estimate of requirements New England is now up to schedule as to receipts of soft coal. In the week ended Nov. 23 increases over the previous week were recorded in the movement from Hampton Roads and Baltimore, and decreases through New York harbor and through New England all-rail gateways.

Bituminous coal dumped at North Atlantic ports decreased from 755,932 net tons in the week ended Nov. 16 to 735,843 tons in the week of Nov. 23. A slight increase at Baltimore was more than offset by decreases at New York and Philadelphia and at Hampton Roads.

The production of beehive coke in the United States in the week ended Nov. 23 is estimated at 521,000 tons, a decrease of nearly 6 per cent. below the previous week and 19 per cent. below the corresponding week of 1917. Although the output of byproduct coke increased the total production of coke declined. Two-thirds of the decrease in output of beehive coke was in the Pennsylvania regions, where shortage of labor continues to be the chief limiting factor. Operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production of 275,497 tons of beehive coke and shipments of 135,550 tons of coal, both representing decreases compared with the week of Nov. 16.

The production of byproduct coke increased slightly in the week ended Nov. 23 from 571,00 tons to 574,800 tons. The percentage of capacity obtained in output decreased, however, from 88.7 to 88.3, and the increase in output is due to a gain in capacity, mainly in Pennsylvania and Ohio. The chief factor limiting output continues to be repairs to plants and affects nearly all sections, particularly Alabama, Kentucky, Massachusetts, New York and Pennsylvania. Capacity production was reported from no state.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running slightly less than for the corresponding week of 1917. Road sales for both immediate and future delivery also were a little below the total for the same period a year ago. The number of customers in the house was about the same as for the corresponding week of 1917. Collections are excellent.

Bradstreet's—Trade and industrial reports are more irregular than at any time since the peace armistice was signed, cancellations of government orders vying in

interest with reports of former non-essential lines starting up or preparing to assume their old importance, and the general tendency is to strike a waiting attitude pending clearer views of future supplies and prices of materials and labor.

Dry Goods Economist—Retailers in all sections of the country report business as excellent, with the principal activities on holiday goods and materials needed for winter wear. The relief from the tension of war conditions is reflected in increased purchases of various commodities. Collections are good. Because of the practical ending of the war, the restrictions of the Council of National Defense which had been put on the sale of holiday goods, and on the employment of extra salespeople, by retailers, have been called off.

The Iron Age—The Steel Section of the War Industries Board has notified all steel manufacturers that it will discontinue allocation of steel on Nov. 30, and thereafter dealings will be directly between Government and other purchasing agents and the manufacturers. A conference at Washington, Dec. 11, between the manufacturers and the Price Fixing Committee may result in extending official prices, with or without change, for another three months, but there is a growing feeling in favor of an early return of the industry to a free basis. Nothing definite has developed concerning the large amounts of pig iron and steel said to be required for Europe. The need is not immediate and the supply of ships is problematical.

American Wool and Cotton Reporter—Until wool values have been definitely established for the readjustment period into which this country is now entering, the woolen and worsted industry must remain in great uncertainty as to future procedure. Canceling of orders for goods has disorganized the industry from top to bottom, and it may be some little time before a satisfactory working basis can be brought about. The Indian cotton crop is 2,000,000 bales short, so the Continent must come to this country for supplies to make up for this lack. As the Indian cotton crop is of low-grade quality, the demand on this account without doubt will absorb large quantities of the low-grade cotton here. Cancellation of Government orders for cotton goods since the armistice is the outstanding feature, offset by the talk of increased freight allowance for the same.

Atlantic Seaboard

BOSTON

Stagnation in the steam trade. Prospect of an end to price-fixing interests the trade. Receipts further reduced. Pennsylvania operators seem indifferent to New England business, yet it is hard to see where tonnage will be placed later. Hampton Roads situation unchanged. New York market dull. Question whether Tidewater Coal Exchange will be continued. Bituminous department of New England Fuel Administration now disbanded. Anthracite receipts show slight increase. Mild weather a sign of steady improvement. Retail prices advanced and restrictions practically off. Municipal distribution in Boston causes comment.

Bituminous—A more lifeless market it would be hard to imagine. With overtime discontinued, and more than a few industries shutting down for two- and three-day periods, not to mention the average reserve supply of twenty weeks, steam coal is today the "druggiest" commodity in trade. It is almost amusing, after the tremendous efforts to save fuel and speed up the unloading of cars, that now, on the verge of winter, it is next to impossible to find a buyer, and the New England railroads are actually storing empty coal cars because their Western connections are not taking them back to the region. Indeed, there are empty coal cars stored on all connecting lines as well, and were it not for Government control there is more than one railroad that because of the extremely light traffic of all kinds would not pay expenses. Movement of coal in this territory is certainly at a low ebb, and there seems no one wise enough to make a safe prediction for the interval between now and Apr. 1.

Should the Government price cease to be effective, as now rumored will be the case, we shall have a highly interesting situation. It is thought that such a move will not in any way create an additional market, but what will become of the thousands of contracts approved by the Fuel Administration and stipulating the last effective Government price as the figure established for the balance of the contract term? In such a situation does any one suppose these provisions, although the essence of the contract, will remain unaffected if the market level is a dollar a ton less? There are a lot of interesting problems to work out, but apparently the fuel authorities have no wish to supervise the process.

Receipts continue the lightest of the year. The average daily movement of bituminous at the five New England gateways has dropped to 260 cars, and railroad fuel has been reduced to 58 cars, a total of 318 cars as compared with 750 in July and August. Water receipts show an even larger reduction. There are agencies at Hampton Roads that are practically confining themselves for the present to making up their debits in the Tidewater Coal Exchange, and chartering almost no bottoms at all. The larger distributors inland have their hands full to find outlet for such coal as reaches the terminals at this end, and every available inch of storage is being used in order to free boats without excessive demurrage. "Orders" are being padded freely. Some glaring cases of shipment being made on requisitions long out of date are the subject of comment among the trade.

While a few operators in Pennsylvania are taking advantage of some of the emergency orders filed with them months ago, a large number of the mining interests have apparently no difficulty in moving their reduced output readily. In the high volatile fields production has diminished to such extent that emergency orders have been obliged to wait. In directions other than New England railroad fuel is in good request, and that has been a reason for the diffidence on the part of operators toward new business in New England. Some of the same shippers have coal due railroads in this territory, but they are headed for disappointment if they expect the coal to be received.

Wagon-coal has now disappeared from the market, so far as this district is concerned. Open-top cars are also being furnished the wagon-loaders, but on this equipment the 75c. extra does not apply, and sales are few and far between on any coal of this origin.

The situation at Hampton Roads continues about the same as when last reported. Bottoms are available about as fast as the coal reaches the piers, and there are now comparatively few cases of detention. The number of boats loading for New England, however, is relatively small, due to the great difficulty of arranging for disposition at this end.

An interesting question involves the future of the Tidewater Coal Exchange. Through our troublous period all will agree that it has made a surprisingly good showing, and undoubtedly railroad management in general will strongly favor its continuance. On the other hand, the coal of individual shippers and agencies loses its identity, and thereby the shippers in many cases are deprived of a great asset in trade. All things considered, the latter interests are likely to prevail in the end, for too much of the competitive feature of the business would be eliminated.

The New England Fuel Administrator announced on Dec. 1 that he relinquished all control of the distribution of bituminous, leaving the steam grades to be handled through normal trade channels. The bituminous staff has therefore been disbanded.

Anthracite—Receipts of domestic sizes all-rail improved slightly the week beginning Nov. 24. The daily average was 337 cars, or 21 more than for the week previous. Water receipts were also somewhat better, although there is room yet for improved shipments by barge from New York.

There are multiplying signs of easier conditions in hard coal generally. There has been a great deal of duplication in entering applications on the part of the general public, and this situation has been extremely hard to police. The recent advance of $1.05 at the mines and the end of the war have accomplished what no amount of regulation could have achieved. The result is a great sifting of the orders now on the books of retailers, and householders beyond number are discovering they have on hand in their cellars enough to see them comfortably through the season. The mild weather has also had a great deal to do with this, and should it continue for a few more weeks and production increase, as we have reason to expect, there will soon be a marked change in the anthracite situation. In many cases retailers who supposed themselves to be far short of the receipts they should have had are finding their current business much reduced in comparison with normal years. The buying of bag coal and fractions of a ton has been very much reduced, due to higher wages and the great extent to which the laboring class bought their six-ton lots as fast as the coal could be had.

It is probable that the fuel authorities will retain supervision of anthracite for some weeks to come, although there are indications here that even this will be of short duration. Emergency coal to the extent of 70 cars daily is moving to the order of Mr. Storrow at the five gateways, but it is apparent that something like the "last call" will soon be issued to those towns that are still behind on their quotas. These latter are communities where the retailers have rather weaker connections, and it is to assist such situations that "free Storrow coal" is still being distributed.

Effective Nov. 29, the Boston Fuel Committee, acting on the advice of Mr. Storrow, allowed an advance of $1 a ton at retail to take care of the wholesale advance applying on coal mined beginning Nov. 1. Boston local prices are now as follows:

Broken, egg, stove, and chestnut	$12
Pea	11
No. 1 buckwheat	10

The local fuel committee has again urged pea coal upon the attention of householders as being an effective substitute for the larger sizes.

Mr. Storrow has now authorized in Massachusetts a general modification of the two-thirds delivery rule, and local fuel committees have been asked to use their best judgment in dealing with local situations. It has been pointed out that it would be desirable to fill existing orders up to two-thirds with the lower-priced coal before any such modification, but when this is accomplished by some method of coöperation between dealers who have less orders and those who have more, the retailers are then to be directed to clean up in full all orders of six tons or less, delivery of four tons on all orders where that tonnage is required, and then delivery up to 80 per cent. on all orders above twelve tons, and finally the completion in full of all orders on the books of dealers. This authorization will be welcomed, of course, by a large number of communities where deliveries have lately been at a standstill because no one would give authority to make deliveries beyond the original two-thirds rule, regardless of the local situation.

The Boston City Council has called in question the methods pursued by the municipal fuel bureau. Those in charge of the latter have apparently been following a safe and sane policy, having regard for the emergency character of the service to be rendered, and some regard also for profit and loss. This is not satisfactory to some of the city fathers, who profess to believe that a municipality can and should sell for less than the regular trade agencies. That the fuel bureau was discouraging sales seems to have caused high dudgeon.

NEW YORK

Domestic sizes of anthracite short, and various industries must not be served with egg, stove or chestnut. Supply of buckwheat and smaller sizes plentiful. Epidemic reported to be lessening. Return of soldiers will be the salvation of the industry. Slump in bituminous narrowly averted. Slow up in production believed to have prevented drop in prices. Additional pools added to coals available for bunker purposes.

Anthracite—Conditions in the New York market are far from satisfactory from the viewpoint of a consumer of domestic sizes. Users of pea and the smaller coals have nothing to fear. There is more than plenty of these sizes to take care of their needs, and many household consumers are using No. 1 buckwheat in their furnaces with egg coal. There is plenty of this size to be had while the quantity of pea coal on hand is said to be unusually large for this season of the year. This is due to the failure of the consuming public to take advantage of the opportunity to secure pea coal, which could be used in most instances instead of chestnut.

An order dated Nov. 22, issued by Reeve Schley, New York County Fuel Administrator, forbidding the delivery of domestic sizes, including pea and larger, to office buildings, banks, retail and department stores, city club houses, loft buildings and numerous other similar classes of consumers, was temporarily modified on Nov. 27 so as to permit the delivery of pea coal to such consumers. At the same time retail dealers are urged to make every effort to substitute broken or pea sizes to domestic consumers who have ordered egg, stove or nut sizes, even to the extent of advising such consumers that they may not be able to obtain the size they have ordered.

Reports from the anthracite fields received here indicate a slight increase in production, with a continued increase in sight

now that the influenza epidemic seems to be letting up, and mine workers who temporarily bettered themselves in other industries are returning to the mines. It is estimated that if the 7500 mine workers to be released by the War Department will return to their former jobs their return will increase the output of coal from 300,000 to 350,000 tons a month.

The Anthracite Committee of the Fuel Administration continues to place embargoes on shipments to communities in various states, directing the distributors to concentrate deliveries to other points in the same states. The Committee also issued an order discontinuing shipments of domestic sizes, including pea, to 216 communities in the Province of Ontario, Canada, and directing that shipments be concentrated to other communities in the Province.

Dumpings at the local docks continue to show a falling off. For the week ended Nov. 29, 4869 cars were dumped as compared with 5599 cars the previous week. For the 30 days of November 21,891 cars were dumped, according to the reports of the Regional Director of Railroads, as compared with 26,616 cars in October and 27,944 cars in September.

The situation as regards egg, stove and chestnut in New York is serious. Dealers are well booked ahead with orders for these three sizes. There is an unusually large supply of broken coal on hand, while pea coal is more plentiful than usual.

With No. 1 buckwheat being delivered to householders, the supply will soon diminish to normal conditions. There is a large accumulation of rice and barley, with some cutting of barley prices reported. Inducements, it is reported, are being made to buyers of these two sizes of an equal quantity of bituminous coal if wanted.

Current quotations, per gross ton, f.o.b., tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individual
Broken	$7.80	$8.55	Buck	$5.10	$5.90
Egg	7.70	8.45	Rice	4.65	5.10
Stove	7.95	8.70	Barley	4.15	4.30
Chestnut	8.05	8.80	Boiler	4.60	
Pea	6.55	7.30			

Bituminous—The influenza epidemic has proved to be the salvation of the situation. To its ravages many shippers attribute the present stability of the market, for without it or some other agency which would have resulted in a curtailing of production, such as the epidemic caused, there would have been a surplus of coal as to have resulted in an overloaded market and a severe cutting of Government prices. At present there is no great surplus of coal and prices are holding steady.

There is a good demand and producers of high grades are having more or less trouble in taking care of their regular trade. This is due in most part to the numerous Government orders and demands for railroad fuel. Cars are in good supply, but labor is short because of illness which is said to be increasing in certain sections of the central Pennsylvania fields. The situation in that section is serious, and producers find themselves hardly able to take care of current needs.

The cancellation of the storage regulations had no appreciable effect on conditions. While the ban has been lifted from many of the so-called non-essential industries, there is a shortage of labor and no need for a full supply of fuel such as would be necessary under normal conditions.

Producers say that many of the mine workers who have been ill from influenza are now returning to their work, but owing to their weakened condition are not able to remain all day. They are, however, showing their willingness to do their part in regaining some of the tonnage already lost. Not much hope is held out by the producers that the tonnage lost will be made up, but the operators hope to increase production sufficiently to take care of current needs and to prevent any further shortage. Considerable will depend, however, upon the time required for industrial conditions to become adjusted.

The report from Washington on Nov. 30 that Dr. Garfield may remove the price restrictions on bituminous elicited little comment among the trade. No one cared to vouchsafe what might or might not happen in such an event.

Improvement in bunkering conditions is expected to follow the adding of Pools Nos. 4 and 10 to that class, giving vessels the choice of Pools Nos. 1, 4, 9, 10 or 11 from which to receive their coal. While some delay has been occasioned by a lack of suitable fuel for this purpose, most vessels have been able to make sailings on time. With shipping increasing now that hostilities have ceased, there is likely to be a demand for bunker fuel that will be hard to meet.

The decrease in production is reflected in the dumpings at the local piers for the week ended Nov. 29, 5037 cars having been dumped as compared with 6121 cars the previous week. For the month of November, 24,582 cars were dumped as compared with 28,568 cars in October and 30,440 cars in September.

Current quotations, based on Government prices at the mines, net ton f.o.b., tidewater at the lower ports, are as follows:

	Mine Gross	F.o.b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite dealers complain of light deliveries. Improvement sporadic. Retailers planning for peace conditions. Stove and nut scarce, pea fairly free, egg plentiful. Inside information is that situation will be met. Steam sizes about normal. New wage demands upon retailers. Bituminous shows some signs of stiffening. High-grade coals scarce. Wagon mines cut. Bunker coal scarce.

Anthracite—Another week of strained relationship between the dealers and their shippers must be recorded. Just as the climax of dissatisfaction appeared to be reached, the largest operating company commenced consigning coal to this market. From present plans, it would seem that the trade of these shippers, which is located chiefly on the Philadelphia & Reading tracks, will receive substantial allotments for two or three weeks. This is not certain, however, and the trade has been so advised, because past experience has shown that preferential instructions may be received from the fuel people for some other points that may change the present arrangements. It is intimated that the present improvement is due to the shutting off of lake shipments, although we hardly believe this can account entirely for the increased shipments by one company, which is continuing a fair volume of tonnage all-rail to lake destinations.

In spite of severe criticism of the Fuel Administration, all hands admit, however, that the regulation of prices and the selling of coal at a fixed margin of gross profit has been most beneficial. Dealers are already discussing the possibilities of coöperation after peace has been finally declared and the Fuel Administration has gone out of existence. They hope to keep their business on the high plane which the administration has placed it, and to eliminate the price cutter, whose methods were often questionable. This city was probably the worst affected community in the country from the point of price-cutting and its attendant evils, such as extension of long credits in order to procure competitive business.

As for the past few weeks, the cry is still for stove and nut sizes, and unquestionably there is less of these two sizes in the yards than at any time since last winter. Every dealer is being tormented by his customers, and the dealers in turn are making miserable the lives of their shippers. With the possible exception of several of the suburban yards, all report as being in very fair shape on egg coal. Pea coal is still in stock in a number of the yards, where efforts are being made to have buyers accept it as a substitute for chestnut.

In talking with representatives of various operating interests, they are most optimistic as to the city's needs being cared for this winter. A number of them predict that they will actually have their sales forces on the road in March soliciting orders, and go further in saying that if the winter is a mild one this will happen even earlier. Some concerns even now occasionally send out their sales forces to ascertain the lay of the land, as it is felt that the business of each concern will be considerably rebuilt when the dealers once more have the opportunity of selecting their shippers.

In the steam coals, buckwheat has recently shown unexpected strength. In this connection one of the local retailers advertised buckwheat as a domestic fuel this week, quoting a delivered price of $6.75 per gross ton. This was the first direct advertising of any coal dealer for over a year. Rice has also improved to a moderate degree, while the same cannot be said of barley. Ever since bituminous became easier the demand for the anthracite steam sizes under buckwheat have fallen off very much.

The retail dealers have lately been confronted with new wage demands by their help. The yardmen want a minimum wage of $26. The men insist on a half-day Saturday, except July and August, when the yards shall be closed, but with full pay. Overtime to be at the rate of 75c. an hour after 5.30 p. m., and time and half time after 12 noon Saturday. Inasmuch as the fuel administration has refused to grant the retailers an increased margin, the demands have practically been rejected by the retailers.

The prices per gross ton c.o.d. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—While the general situation is still somewhat easy, there is a growing scarcity of real high-grade coals. There is a good supply of ordinary fuel, but even this coal is being moved with less effort than during the past three weeks. Reports are occasionally heard of price shadings on this latter coal, but even this is growing less. One factor tending to a tightening of the situation is that many of the wagon mines are almost out of business, due to their inability to get cars. The railroad authorities have practically denied them a supply of box-cars, claiming they have greater need for this equipment in other lines.

At the piers there is a scarcity of coal in bins Nos. 9 and 10. This is stoker coal of the highest grade, such as South Fork and Scalp Level. Many ships are standing idle waiting for fuel, and it is stated in the upper ports there were as many as 100 waiting at one time. They can obtain the ordinary coal, but are insisting on the best.

BALTIMORE

Every day sees an increase in soft-coal offerings, although best grades are still held tightly. Hard-coal situation aided by mild weather.

Bituminous—An easing bituminous situation is in evidence. For the first time in months there are a number of men here with coal to sell or who will have coal to sell shortly; and many letters are coming through daily from mines offering coal to jobbers or consumers, or feeling out for future relations as soon as additional war contracts are announced. Box-car coal has been almost completely kept from the market for a few days, and in some regions the Baltimore & Ohio placed an embargo against movement of that character.

The receipts of open-top coal here, and some little box-car coal, chiefly on orders of some little standing, have been ample to care for all needs. Better grade coals are still tightly held, however, through the fact that the Government has not released them to the general market. In this connection it is a little odd to know that while such coals are not available in any quantity as yet for the open market, that at times there is a big accumulation here for Government account. In some cases several hundred carloads of high-grade coal have remained on sidings and at terminals here for many days at a time before being moved. At one time last week one Government pool here had over 400 carloads of high-grade coal standing.

Reports from the mining district are to the effect that production has dropped off because miners will no longer hustle as they did under the lash of patriotic endeavor. Two-, three- and four-day-time men are again developing, and the higher wage scale of these days seems an inducement in many cases to do only a part week. For the time being, however, this cut in production has probably aided materially in stabilizing the market and preventing quotations here from going below the Government maximum.

Anthracite—The hard-coal situation here has been made a little easier than expected through the continuance of mild weather. The estimate that around 100,000 tons still remained on the books undelivered, and that as much more would like attention at least in part immediately, has been softened by the fact that a number of additional consumers have been given one- and two-ton lots. Stove and nut coal remain very scarce here, and those who can only use those fuels are in more serious plight than consumers who can use egg or pea.

Lake Markets

PITTSBURGH

Market shows no softening. Celebrations and influenza cut deeply in production. Wagon mines still operating.

Prospects of the Pittsburgh coal market dropping below the maximum Government limits have receded almost to the vanishing point, the curtailment in production in the past three weeks disclosing what light stocks were carried by consumers tributary to the district. In this regard the situation is different from that obtaining with much territory served by Ohio and more western districts. The increased demands made upon the Pittsburgh district for coal for lake shipments, beyond the original quota for the district, prevented any material accumulation of Pittsburgh coal by consumers.

Production of coal in the Pittsburgh district had reached a rate of about 1,200,000 net tons a week, when lake shipments were at from 300,000 to 350,000 tons a week. Owing partly to the peace celebration and partly to increased effects from the epidemic of influenza, production was only 700,000 tons in the week ended Nov. 16, the week of the peace celebration, and there was an increase only to 800,000 tons in the following week. Production last week, with a holiday, is not reported yet, but was probably less than 800,000 tons, as working forces on Friday were not as large as in the first three days of the week.

Shipments of Pittsburgh coal have been shut off except to certain specified consumers, including railroads, byproduct coke ovens, public utilities and retail dealers, but application can be made for coal by consumers who show that they have no stocks to draw upon. The byproduct ovens are but indifferently supplied, and have little by way of stocks.

There has been no important cessation of operation by wagon mines, and they are still obtaining full limit prices. By reason of the extra trucking charge allowed, on which a profit is made, their selling prices are higher than those of rail mines, and if there is to be any decline in the regular Pittsburgh market it will be preceded by a closing of many of the wagon mines. Thus, apparently the trade would have ample warning of a prospective market decline; yet there are many consumers even now seeking to buy at cut prices, entirely without success, and the market is quotable firm at Government limits; slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district.

CLEVELAND

Excepting only an occasional holdover cargo, the lake season has come to an end. Steam-coal users, for all practical purposes, are not buying a ton, seeking to use up the high-cost fuel in their stockpiles. Domestic users have supplies sufficient to tide them over the turn of the year, when they believe prices will recede.

Bituminous—Big blocks of low-grade coal, comprised mainly of the outcrop from stripping operations, have been thrown on the market in northern Ohio at from 50c. to $1 under the Government maximum. A concession of 70c. seems to be the favorite figure. While it no doubt is true that a few scattering operators, alarmed at seeing surplus piles at the mines increasing, have made slight concessions on standard No. 8 coal, the great majority of operators appear to be standing pat. Declarations that they will shut down their mines before they will shade the Government schedule are frequently and firmly made.

The steam-coal market seems to have developed into a tug between buyers and sellers. Industrial plants now have the labor to bring in fuel from stockpiles and are not buying at all. The few plants that must have spot supplies are buying from hand to mouth. Opinion is unanimous among steam-coal users that prices are going down. Operators on the other hand are just as insistent that under present conditions they cannot make much of a concession before they reach the deadline on profits. The weight of the "bear" argument is that if enough buyers hold out long enough prices will tumble. Stripping property operators and producers of No. 6 and other so-called low-grade coal have succumbed, and are making many of their proffers on this basis: "If you won't consider this block at so much off the Government maximum, what will you offer for it?"

Car supply at Ohio mines has picked up markedly, and now is less than 15 per cent. short. So far as production and shipments are concerned, the supply is 100 per cent. The end of the lake trade for 1918 has resulted in some gondolas being put in storage. The railroads themselves now are taking very little fuel for they, like the industrials, have stockpiles to reduce. With Thursday out for Thanksgiving, the hunting season on and influenza not yet entirely bested, last week virtually was a three-day one. Operators are content with such a situation, not pressing their employees or seeking to obtain more than a nominal output, with the market so much narrower.

Cold weather that set in early last week made the domestic market much more brisk, but not to any great extent. Domestic consumers have half their winter's coal in, generally speaking, and are showing a disposition not to buy the other half until necessity impels. Retailers are seeking business just as earnestly as in pre-war days, but without resorting to cut prices except in occasional instances.

Anthracite—County Fuel Administration officials have definitely stated the cessation of hostilities will not effect an increase in the district's allotment of anthracite. Receipts continue nominal and, if anything, are decreasing. Domestic consumers are preferring the better grades of No. 8 coal now available to the No. 1 buckwheat they are offered.

Lake Trade—The Northwest's 28,000,000 tons of bituminous was floated by the official ending of the lake season Nov. 23, and the daily loadings at Lake Erie ports last week, which had to be specially arranged through the Coal and Ore Exchanges, averaged less than 40,000 tons, or four vessels. Anthracite will be shipped from Buffalo so long as the carriers are operated.

DETROIT

Heavy stocks of bituminous at industrial plants and in yards of retailers prevent normal seasonal business. Anthracite supply deficient. Lake movement drags.

Bituminous—Due to the somewhat frenzied buying of a few weeks ago, many of the leading users of steam coal and numerous retail dealers find they are holding larger stocks than they desire to carry. This situation has cut down the volume of buying and produced a market condition more sluggish than is customary at this season of the year. Jobbers have been able to do very little business, aside from that coming from steam-coal consumers whose storage facilities are restricted and who therefore find it necessary to operate on a basis of hand-to-mouth.

The circumstance that considerable of the coal in stockpiles is the product of mines in Indiana and Illinois that are not producers of the best coals in those states is said by some of the jobbers to be the probable explanation of why a number of the stockpiles have taken fire. The fact that much of this coal has also found its way into yards of retailers is one of the reasons suggested for slow absorption by household consumers.

Such buyers who have been compelled to forego the exclusive use of anthracite in heating plants feel that if bituminous is to be substituted, it should be a high quality of bituminous from West Virginia and Ohio, instead of the lower grade coals. The retailers who are loaded up with the Illinois and Indiana coal, however, are not now in position to supply the better class of stock.

Anthracite—Householders are still clamoring for anthracite, while the supply remains light. Receipts in the local market in November are much short of the movement in October. The state fuel administrator has given warning that chestnut and stove sizes are to be reserved to enable distribution of another two tons to users of baseburner heaters.

Lake Trade—Loading of coal for lake shipment was practically finished on Nov. 23. There are, however, a few shippers who are still striving to fill shortages on their commitments. Because of the active demand for vessel capacity for holding storage cargoes of grain, the supply of tonnage to be had for moving coal is becoming daily more limited. Anthracite forms a considerable proportion of the present lake shipments.

COLUMBUS

The coal trade in Ohio is still rather weak, more especially in steam grades. Consumers are using surplus stocks and are loath to buy heavily at this time. Some price cutting results.

The Ohio trade is in a period of readjustment, which is affecting every department of the industry. The domestic trade is least affected because of a good demand for lump among certain dealers. Retailers look forward to a good trade as soon as weather conditions are more favorable, but so far there have been no cold snaps to stimulate trade. Reports show that fully 75 per cent. of the fuel required in cities has been stored by householders. In the rural sections, however, it is believed that no more than 35 or 40 per cent. has been stored. Consequently, dealers in the smaller towns are looking for a good trade in the near future. Retail prices have not been cut, and there is no indication of shading soon. The so-called fancy grades, such as New River and splints, are in the best demand. No Pocahontas is coming into the local market. Anthracite is practically out of the market. Dealers have considerable mine-run, which will probably prove an elephant on their hands.

The steam business shows the most weakness. Steam users have reserve stocks to last for two to five months, and are thus not inclined to buy for the future. As a result there is a slight overproduction of mine-run and slack. Some mines have been closed down for want of orders, and others will probably follow suit unless conditions are radically changed. Railroads are not taking as much fuel as formerly. On the whole, the steam trade is in bad shape.

The lake trade is now practically over, although some coal was loaded during the past week. The cargoes were generally those of boat lines controlled by shipping companies. The Northwest is now well supplied with fuel, and no famine is anticipated in that section. The season was one of the most active in the history of the lake trade.

Production in Ohio fields is still curtailed by influenza. In addition, lack of orders is cutting into the output. As a result of the slowing down, the production in the Hocking Valley field is estimated at 60 per cent. Pomeroy Bend is producing about 55 per cent., and the same figures are reported from Cambridge and Crooksville. Eastern Ohio has been having a good car supply, and the output is nearly 70 per cent.

CINCINNATI

Colder weather has stimulated demand somewhat, but industrial demand continues cautious. Supplies are improving, with better conditions at mines.

Decidedly colder weather during the past week, the most wintry of the season so far, resulted in the usual stimulus to business, as the demand for coal for heating purposes developed from both domestic and other consumers who had not stored fuel during the summer and early fall months. Retailers are well supplied, however, and the flurry did not cause any great excitement among jobbers and operators' agents. Discussion among the trade has centered principally on the prospects for industrial business during the remainder of the winter and next spring, as cancellation of war orders among some branches of industry has resulted in some alarm regarding the future of these industries.

Reports from Washington indicate that there will be come effort made to prevent undue hardship on concerns having war contracts, but this is not expected to enable them to continue operating on the same full basis which has been the case for the past year. In lines not dependent on the war, activity promises to be on a normal scale, if not larger, and consumption of fuel will accordingly be up to the usual mark.

On the whole, prospects for the coal business are taken as satisfactory, although the unbroken record of an excess of demand over supply which existed last winter is not expected. More vigorous sales work is therefore in prospect than has been necessary for more than a year, and the trade is getting down to business under conditions approximating those prevailing before the war.

LOUISVILLE

Colder weather only prospect for increased business at the present time. Domestic demand very quiet, industrial demand quieter, and general market dead. Some price cutting reported.

The steam demand represents merely hand to mouth, or actual requirements of consumers. Everyone apparently has stopped stocking, and the general opinion of consumers now is that they can get all the coal they want, when they want it. With industrial conditions unsettled, the steam consumers do not care to tie up money in coal. Many industrial plants are reducing working hours from ten to nine and even eight, including some of the railroad shops. This is naturally reducing steam consumption, as industrial demand of all kind has slacked off since peace was declared and cancellations of orders started coming in.

In the mining sections things are virtually at a standstill. Many new companies, incorporated recently and planning developments, are holding up until they see

how things are going to work out. Several concerns which had taken bids on additional buildings have held up contract awards. Many of the larger mining companies have no business on hand and very little in sight. While few companies are reported to be laying off labor, at the same time no one is replacing men who are leaving, or making any attempt to secure hands or get back men who went into other industries. Unless the demand picks up shortly it is believed that some of the mines will be forced to cut working hours and lay men off.

The powder plant at Nashville which had been taking a large volume of coal from western Kentucky has reduced operations materially, and this has thrown an additional supply on domestic and steam markets which had been figured for Nashville.

The operators of the Pittsburgh and West Virginia fields, who for some time have been forgetting river coal and making no attempt to ship to lower Ohio and Mississippi River points, are showing interest in recruiting barges and towboats to handle river coal. Some fair shipments have come down the Ohio whenever boating stages would permit.

Several reports have been received during the past few days relative to price cutting. A few small retailers have been cutting prices 15c. to 20c. under Government prices in order to secure business. Wagon mines have also been cutting prices in order to get business on inferior coal and to dispose of box-car shipments which are not wanted. However, the open-car supply is improving so rapidly that box-car shipments will not be made much longer.

BIRMINGHAM

Steam trade requirements fair, but no insistent demand except from the railroads and public utilities. Domestic holds up strong, with no improvement in the supply. Production from 75 to 80 per cent. normal.

Steam coal consumers in industrial lines appear to be fairly well stocked on coal and are content with receiving their regular stipulated shipments, and in some cases have expressed a desire for a curtailment. However, the railroads and public utilities seem to be short and are taking all the coal that is available for application on their requirements. They are probably looking ahead to the Christmas holidays, as it is pretty generally anticipated that mine workers will celebrate more extensively this season than usual, and there will be a heavy slump in the output. Local coal men are of the opinion that the trade will hold up well through the coming winter and that there will be ample demand to absorb the anticipated production. The Fuel Administration has lifted the ban on coal storage and supply for industries classed as non-essential during the war, which should increase the demand to some extent.

Domestic trade is active and there is a great scarcity of coal of this grade. Retailers have not accumulated stocks to any extent, as consumers have kept up a lively demand since Apr. 1 and there is far more coal in storage than ever before in this section.

Production is improving slowly, owing to the great extent to which idleness exists on the part of the mine workers, and the output for the week ending Nov. 16 reached the low level of 329,190 net tons, a decrease of some 19,000 tons compared with the previous week.

Director General William G. McAdoo spent a short time in the city Thanksgiving day, and during his visit reviewed with representatives of the civic associations the proposed plans for Warrior River development, which have been favorably reported upon by Government investigators.

Coke

CONNELLSVILLE

Increased curtailment in production, leading to blast furnaces banking. Terms of contracts for first half. Market firm.

The curtailment in Connellsville coke product that began in October was at first not felt by blast furnaces, which seemed still to be adequately supplied. The blast furnaces had some stocks, but they averaged less than a week's supply. As production has continued to decline, the blast furnaces have been seriously affected. The Carnegie Steel Co. alone has banked five blast furnaces on account of insufficient coke supplies, and all the banked furnaces are tributary to the Frick ovens in the Connellsville region. The company has blown out one stack at Ferrell, for rebuilding, thus releasing some byproduct coke, or the situation would be worse. The company now has 50 furnaces operating, with five banked and four out of blast.

During September production of coke in the Connellsville and Lower Connellsville region averaged fully 340,000 tons a week, there being a progressive decline, until at the end of October the rate was under 300,000 tons. Week before last production was under 250,000 tons, chiefly on account of influenza, and last week's production, with a holiday intervening also, may not have been over 225,000 tons.

Among coke consumers there was an expectation the end of the war would be followed rather promptly by a decline in the coke market from the Government maximum limits. If a decline really was due, it has been forestalled by this sharp decrease in production, and there has also been a decrease, although a relatively slight one, in the production of byproduct coke. The majority of blast furnaces that use merchant coke have made contracts at one time or another for their supplies for the first half of the new year, the usual form of contract specifying the Government price at time of delivery, or if there is no Government price then the open market obtaining. There has been so much of this contracting that there is a little question whether, in the event of Government price control being withdrawn, there will be enough open market business to establish clearly an open market price from time to time. The market is quotable very firm at Government limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over ¾-in., $7.30; clean screenings, over ½-in., $5.50, per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Nov. 23 at 242,105 tons, a decrease of 17,825 tons, and raw coal shipped at 165,796 tons, a decrease of 19,444 tons.

Middle Western

GENERAL REVIEW

Coal production falling off. Buyers not in market and producers do not expect any change in market conditions before Jan. 1.

A glance at the recent Government reports on tonnage of coal produced in the United States shows a big decrease in production. This general tendency holds true in the producing districts of this territory, as the figures in the district representative's office show that the tonnage for this week will be even smaller than that of the week previous. Under the circumstances, this decrease is a good thing, as it is keeping the market from becoming utterly demoralized.

Operators have made up their minds to close their mines one or two days a week, rather than operate at full time and have unsold coal on their tracks at night. This decrease in the production figures for Illinois and Indiana has had little effect on the buying public. Instead of being alarmed over the situation, they are not interested and are not purchasing coal. The state of mind of the average purchasing agent appears to be that he now has an opportunity to burn the storage coal he laid in during the summer, and has therefore cut off all further shipments of coal.

The gist of interviews with a number of the larger operators appears to show that the general opinion is that the coal industry in the Mid-West district will have to face an unprecedented hardship until say from Jan. 1 to Mar. 31. After that period the optimists claim that the reconstruction program will be well under way, and consequently will work a relief to the operators. In the meantime, not much change in market conditions is to be looked for, at least before the first of January.

CHICAGO

In spite of cold weather market conditions are sluggish. Anthracite situation improving.

Chicago had one or two days of cold weather last week, but it was not enough to make much change in either the steam or retail situation. Both the householders and the large industries have enough coal on hand to last for some time, and, contrary to previous conditions, the market will not be subject to much fluctuation on account of weather conditions. During the height of the cold spell there was little demand for domestic coal, either the cheaper grades or the best to be had from the Southern fields of Illinois.

The anthracite situation is perhaps a little better than heretofore, as most of the dealers are getting all the anthracite they have room for. The trouble appears to be that once the dealer receives his hard coal, he is unable to dispose of it, on account of the many rules and regulations devised by the state fuel administration.

ST. LOUIS

The market continues quiet with mild weather. Plenty of cars, transportation good, and no demand for steam or domestic. Railroad coal movement good. Prospects not encouraging.

The St. Louis market continues heavy, with nothing encouraging to look forward to, unless it be some extraordinarily severe winter weather. The local retail demand is practically nothing. A little coal is moving, but the tonnage is so small that it is not a factor. The current steam business helps a little, but in a general way there is no coal coming into St. Louis to speak of. The same condition applies to the country business.

Large steam plants are using up their surplus, realizing that no buying on the part of a large number has a tendency to bring the market down, so that when the time is ripe they can begin to put coal away, if necessary. One large plant is taking one half of its current needs out of the storage pile and buying on the open market at greatly reduced prices.

Screenings are heavy from all fields and in the Standard market are bringing about $1.50 at the mine. Carterville screenings are plentiful, and here and there a slight break in the Government price is reported.

The railroads at this time are the lifesavers in the Standard coal fields, and this applies also to the Mt. Olive and Carterville fields. The tonnage of railroad coal the past week has increased and it is likely to from now on. Some large contracts are being made right now that will carry through to the first of April on railroad business, running into several hundred thousand tons from the Standard field.

Throughout the field the tonnage is increasing at the individual mines, although it means less days of work, because the miners affected by the influenza epidemic are returning to work. In the Mt. Olive field the mines are working exceptionally well, and a good tonnage moves north.

In the Carterville and Du Quoin fields there is a slight surplus of coal. Prices are holding remarkably well. Railroad tonnage here continues good, cars are rather plentiful and the supply of men is getting better.

There are no outside coals coming into the St. Louis market except a little Arkansas, and this does not run over ten to twelve cars per week right now. The price of this coal is so outrageously and unreasonably high that the public in St. Louis will not stand for such imposition.

Coke is plentiful, with no buyers, because the price is too high.

With the exception of Standard coal prices, on which screenings are $1.25; 2-in. lump, $1.75; 6-in. lump, $2, and 2 x 6 egg at $2, and Mt. Olive lump slipping a trifle, there is no change from the Government maximum prices, which are, f.o.b. mine per net ton:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.75	$2.55@2.75	$2.40@2.70
3x6-in. egg	2.55@2.75	2.55@2.75	2.40@2.70
2x3-in. nut	2.55@2.75	2.55@2.75	2.40@2.70
Washed:			
No. 1	3.05@3.20	3.05@3.20	.....
No. 2	3.05@3.20	3.05@3.20	.....
No. 3	3.05@3.20	3.05@3.20	.....
Mine Run	2.35@2.50	2.35@2.50	2.20@2.30
Screenings	2.17@2.32	2.17@1.32	1.50@1.60

Special preparation on Carterville is 10 cents extra.
Williamson & Franklin Co. rate is $1.10.
Other fields 95 cents.

General Statistics

BALTIMORE & OHIO

The following is a statement of the coal and coke tonnage moved over the Baltimore & Ohio system and affiliated lines during the month of July, 1918, as compared with the corresponding month of the previous year:

	1918 Tons	1917 Tons
Coal	4,564,857	3,259,844
Coke	290,772	316,557
Total	4,855,772	3,576,401

COAL AGE

Volume 14 New York, December 12, 1918 Number 24

That We May Continue Joyful

THANKSGIVING day has come—and gone. We have offered our thanks for a bountiful harvest; but that bounty of nature, cut and garnered, will do us little good if by lack of care we let it heat, sour and spoil. We have rendered thanks for the victories of the war, but we must never forget that what is gained by valor is often lost by poor diplomacy and the mutual jealousies of the victors.

ABOVE all, we gave thanks for the new spirit of mutual understanding, perhaps the best gift of the war and also the most fleeting. That unity of hearts may well disappear as mysteriously as it came. The war found capital and labor organized into bodies to wage an economic conflict, but the contending parties quickly forgot their old enmities as they became absorbed in their new duties. The keynotes of the war are not hatred and violence, but rather mutual respect and helpfulness.

LET us be careful lest this good grain garnered in generous measure, but carelessly housed, furnish us with nothing but impotent regrets. We have learned since the war so much as to the essential uprightness of all men—manual laborers, mental workers and capitalists. We have acquired a generosity which has surprised us all. We have renewed our beliefs in the importance of all those things the value of which cannot be expressed in money.

We have seen that under favorable conditions there are the possibilities of good in all assemblies of men, whether the men thus assembled form labor unions or employers' associations. The generous spirits of men refuse to permit them to confine their discussions to the promotion of their selfish interests. We have learned that if we only appeal to the good, that the good is there; that the making of agreements can be such a pleasant occasion as to be the source of friendships rather than the occasions of embitterment. We have been surprised by the small part played during the war by narrow self-interest.

We have seen the influenza come and take nearly six times as many victims as the war, and from that fact we have learned how important is medical attention and universal education in the art of prophylaxis. We have learned the dangers of having a population of foreigners which we have done little to welcome and nothing to educate. We have been encouraged by the patriotism of the alien and by his ready appreciation of the little we have done to win him.

LET us keep all we have gained, every foot of the spiritual domain we have conquered, all the joy of giving, all the democracy, all the faith in others, all the largeness of vision, all the depth of our Americanism, all the pleasure of our larger world consciousness. The things which the war has given us are big, the biggest of all things. We have drunk deep of the new elixir of life. Let us not willingly go back to the small beer of the days before the war—to its squabbles, its doubts, its meannesses and its animosities. Thanks to the Germans, we have learned how bad is evil and how glorious is our heritage of kindliness and good will.

Use and Abuse of Electric Headlights on Mining Locomotives*

By K. W. MACKALL
Syracuse, N. Y.

THREE different types of headlights are in use on mining locomotives today, and each has certain characteristics peculiar to its type. A thorough understanding and application of these characteristics will overcome most headlight troubles. There is nothing mysterious about a headlight. It is simpler than the motors, controller, wiring, etc., which comprise the electrical equipment of a mining locomotive, but it seems to be abused more than all the rest of the machinery combined. It is unfortunate that not only the motormen but even the men who couple cars consider themselves competent to "fix" headlights instead of leaving that to the shop electricians.

The luminous arc headlight possesses the inherent advantage of high illuminating efficiency, owing to the composition of the lower electrode. It is the most efficient of all types of headlights commercially available, unless it is possible to operate the extremely low voltage, high-current Mazda lamps, such as the 6-volt, 18-amp. lamp. The maintenance cost of this headlight is low, since it requires no inclosing globe for the arc and the upper electrode is practically non-consuming, while the lower electrode has a life of from 125 to 150 hours of burning.

Owing to the fact that the upper electrode is practically non-consuming, the arc is always maintained at the focal point of the lens or reflector. Adjustment of this upper electrode is necessary only once in two or three months' time.

A headlight of this type has the disadvantage that a certain amount of fumes that must be wiped away are given off from the arc, and the headlight is not quite so simple as an incandescent headlight because it has several moving parts. One other disadvantage which it possesses in common with all arc headlights is that the natural travel of the arc around the electrodes causes the beam to wander slightly from side to side, but its many advantages more than offset these.

One of the greatest causes of poor illumination from luminous arc headlights is improper care of the upper

FIGS. 5 AND 6. ARC COMPARTMENT AND MECHANISM COMPARTMENT OF LUMINOUS ARC HEADLIGHT

electrode. This electrode should be adjusted once in every two or three months' time, but I have seen cases where they have not been adjusted for perhaps a year. This means that the upper electrode is burned away from $\frac{1}{2}$ to $\frac{3}{4}$ in. and the arc is struck that distance above the center line of the headlight, resulting in poor track illumination.

The result of this inattention to the seemingly unimportant headlight is obvious to all, and I have seen headlights operating under conditions which would bid fair to lay up a locomotive if another piece of the equipment upon it were run in a similar manner.

The earlier forms of luminous arc headlights were of the single compartment type; that is, the arc and mechanism were in the same compartment (see Fig. 4). Later development brought out the two-compartment headlight (Figs. 5 and 6). Fig. 5 shows the front compartment containing the electrodes, between which the arc is struck. This compartment is hermetically sealed from the rear compartment (Fig. 6), which contains all the operating mechanism. In this type of headlight the fumes given off by the burning arc cannot accumulate on the mechanism parts. Therefore, the headlight works more freely and gives practically no trouble from a "sticky" mechanism. The chief advantage of this two-compartment headlight is that the mechanism is out of the way and, therefore, unauthorized persons are not so liable to tamper with it. This advantage sometimes works to a disadvantage, for when major repairs are necessary, the headlight must be entirely removed from some locomotives, because it is mounted too close to the frame to permit repairs to be made. Notwithstanding this, the two-compartment headlight has proved more reliable and more economical than the single-compartment headlight.

The connections are traced as follows (see Figs. 5 and 6): Starting at binding post *A*, the positive side, the current flows through the magnet coil *B* and then to the insulated stud *C*, through the partition. This insulated stud connects directly with the upper electrode *D*. Current then flows through the lower electrode *E* to the flexible connector *F*, to the negative terminal post *A*. It is essential that these connections be observed, particularly the polarity.

The external connections are simple, as everything is connected in series. The circuit runs (Figs. 7 and 8) from the trolley through a protecting fuse and a resistance to the contact switch, which may be either one-way or two-way, according to whether one or two headlights are used per locomotive. From this switch current flows through the headlight back to a negative receptacle, which is grounded. Plugs and receptacles have been found advantageous for connecting the headlight to the circuit, since it is then possible to change to the proper headlight polarity, if the trolley for any reason becomes negative.

The headlight is shipped from the factory carefully adjusted for proper operation. If repairs are necessary, the mechanism should be readjusted as follows: First of all, loosen the magnet stop screw *C* (Fig. 9) and raise it so that it will clear the top of the armature *B*. Lift the armature *B* with the finger until the clutch *D* engages the stop *E*, and then raise or lower the clutch stop *E* until the arc length is from $\frac{5}{16}$ to $\frac{3}{8}$ in. The arc length may be measured (not guessed at) from the back by measuring the distance between the bottom of the clutch *D* and the top of the support *F*.

A final check should be made by actually measuring the arc length itself in the front compartment. Still holding the armature *B* so that the clutch *D* strikes its stop *E*, the magnet stop screw *C* should be lowered until it touches the top of the armature *B*—a slight pressure on the armature will give evidence of this touching.

Now back the screw *C* out about a half to a full turn and lock it in place. There must be a slight clearance between the bottom of the screw *C* and the top of the armature *B*. To be sure there is a clearance, let the armature *B* drop and raise it again, first holding a piece of tissue paper between the clutch *D* and its stop *E*. When the armature *B* is held in the top position the tissue paper should be held tightly between the clutch *D* and its stop *E* and should tear rather than pull out.

The idea is to obtain the proper arc length, with the clutch *D* striking its stop *E*, and then to have a slight clearance between the armature *B* and the stop screw *C*. If this clearance is too great, it will materially weaken the pull of the magnet, particularly at low voltages.

In order that the arc may be in the focal point of the lens, the bottom of the upper electrode should be $1\frac{1}{2}$ in. from the lower edge of the holder in Types MLD and

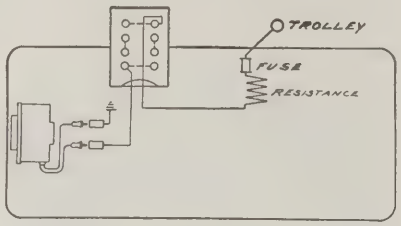

FIG. 7

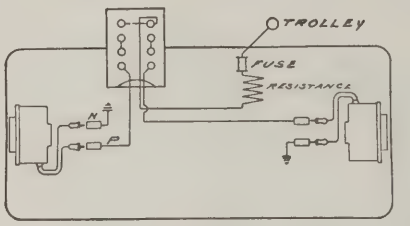

FIG. 8

FIGS. 7 AND 8. DIAGRAMS OF CONNECTIONS EMPLOYED WITH STATIONARY HEADLIGHTS
Fig. 7—Wiring diagram for stationary headlight with single-end equipment. Fig. 8—Wiring diagram for stationary headlight with double-end equipment

MLK headlights, while in Types ML and MLF this distance should be 1¼ in. The lower electrode should be so placed that its upper end is 1 to 1¼ in. above the upper edge of its holder. The proper knowledge and application of these adjustments will insure satisfactory operation of the headlight.

When the current is off, the electrodes are together. At the instant the current is switched on, the magnet coil is energized and lifts the armature. This motion is carried through the clutch rod to the mechanism and the arc is struck and maintained. The arc length remains practically constant since the rate of consumption of the electrodes is slow. Natural circuit interruptions, such as circuit breakers, sectionalizing switches, etc., cause the arc to break often enough to prevent its becoming too long.

The electrodes of luminous arc headlights burn a long time. The upper, positive electrode is made of copper and has a life of 3000 hours. Every two or three months it should be adjusted so that its lower face is the proper distance from the bottom of its holder. The lower, negative electrode has a life of 125 to 150 hours on 4-amp. headlights and 200 to 225 hours on 2-amp. headlights, and after ten hours' burning should be adjusted so that the burning end of the electrode is 1¼ in. from the top of its holder.

The arc voltage is 80 in both the 4-amp. and the 2-amp. headlights, and the difference between the arc voltage and the line voltage is taken up in the dead resistance which is connected in the circuit. To insure the proper arc voltage it is only necessary to keep the arc $\frac{5}{16}$ to $\frac{3}{8}$ in. in length.

The upper copper electrode is positive and the lower electrode negative. This polarity should be maintained. A reversal of polarity will mean poor operation, since the arc will be dim and unstable. Every arc is characteristic of its negative electrode. In the luminous arc headlight the negative electrode is a magnetite composition which burns with a brilliant white light.

When a new lower electrode is put in the headlight, it should be burned for about 5 min. before being sent out on a trip. This time is necessary to burn off the iron cap on top of the electrode, during which period the arc is somewhat unstable. Two leads with plugs are furnished with all luminous arc mining headlights so that proper polarity may be maintained at the headlight regardless of trolley polarity.

The headlight casing is ventilated and the air outlet so baffled that the arc cannot be blown out nor can rain beat in. On top of the casing is a ventilator, at the back of which is a long narrow opening. As the locomotive runs along, the air rushing past the sides of the headlight creates a partial vacuum in the ventilator, thereby causing the fumes to flow out of the casing.

About once a day the headlight should be cleaned; that is, the deposit from the electrodes should be wiped or blown from the lens and casing. In nearly every car shop compressed air is available, and this can be used to good advantage in blowing the deposit away. The mechanism entirely in the rear compartment should be kept free, but no oil should be used. The front door should be kept closed always and a broken lens replaced immediately. This is to prevent wind from blowing out the arc. A test for free operation of the mechanism is to switch the current on and then off again. The lower electrode will immediately come up against the upper with some little force.

Carbon arc headlights have the advantage of low initial cost and also that no fumes are given off by the arc to depreciate the reflector or lens. They are a reliable headlight and will operate for long periods of time with practically no attention to the operating mechanism. However, the lower efficiency of these headlights as well as the higher maintenance cost as compared with the luminous arc headlights, have caused them to take a position of secondary importance on

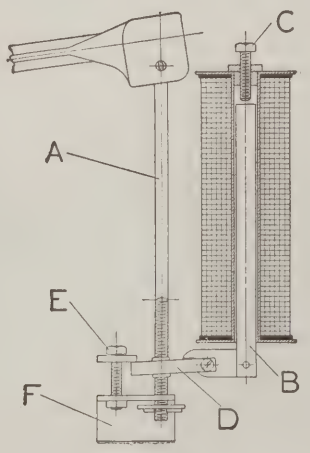

FIG. 9

FIG. 9. CLUTCH MECHANISM OF LUMINOUS ARC HEADLIGHT

haulage motors. This high maintenance cost is due to short-life electrodes and the necessary inclosing globe. Since both the upper and lower electrodes are consumed during the burning of the arc, it is necessary that the arc be readjusted to the focal point of the reflector every two or three hours. This adjustment is accomplished by moving the lower electrode up to its original position.

The carbons in all 4-amp. headlights burn 30 to 40 hours before they have to be renewed. In the 2-amp. headlights the carbons burn 50 to 60 hours. Only straight, fine-grained carbons should be used.

The inclosing globe is made of heat-resisting glass, carefully annealed to prevent cracking or melting. The ends are ground to insure perfect fit against globe seat and cap.

Figs. 14 and 15 show the external connections usually employed with carbon arc headlights. These connections are simple, since everything is connected in series. The circuit runs from the trolley through a protecting fuse and a resistance to the control switch, which may be either one-way or two-way, according to whether one or two headlights are used per locomotive. From this switch the current passes through the headlight to the ground.

The following adjustments are carefully made at the factory before headlights are shipped, and they should be maintained when making repairs. In the vertical carbon headlight the clutch picks up against the spacing bushing *Q* (see Figs. 16 and 17), which regulates the length of the arc. The stop screw *S* is adjusted so that there is a slight clearance between it and the top of the armature *C*. This adjustment is secured by holding the armature *C* up and moving the screw *S* down until it touches the top of the armature, and then backing the screw out a half to a full turn and locking it in place.

When replacing the reflector or the magnet coil *N*, care must be taken to see that the reflector does not touch the upper electrode holder. This can only come about through a variation in castings. To compensate for this variation the entire mechanism may be rocked slightly by means of the screws *T* and *T'*. When replacing the magnet coil *N*, the yoke must fit the coil head snugly. If the coil is allowed to "ride up," it may not center itself around the armature. It is always a good plan to bend the ends of the yoke together and spring them apart when putting the coil in place.

The internal connections of the headlight are simple and should be observed. The positive plug of the arc circuit terminates at the binding post *A*, to which is also connected one end of the magnet coil. From the other side of the magnet coil the current flows through the upper carbon to the lower carbon. The knurled wheel *K* is under spring tension and bears directly on the lower carbon. The entire lower carbon-holder is grounded. (See Figs. 16 and 17.)

In the Type M carbon arc headlights the arc current is from 4 to 4½ amp., and in Types V and VR headlights the current is from 2 to 2½ amp. The arc voltage of all headlights is 70 to 80 volts. To maintain this arc voltage it is only necessary to keep the arc length $\frac{3}{16}$ to $\frac{1}{4}$ in. The difference between the arc voltage and the line voltage is taken up by a dead resistance connected in the circuit.

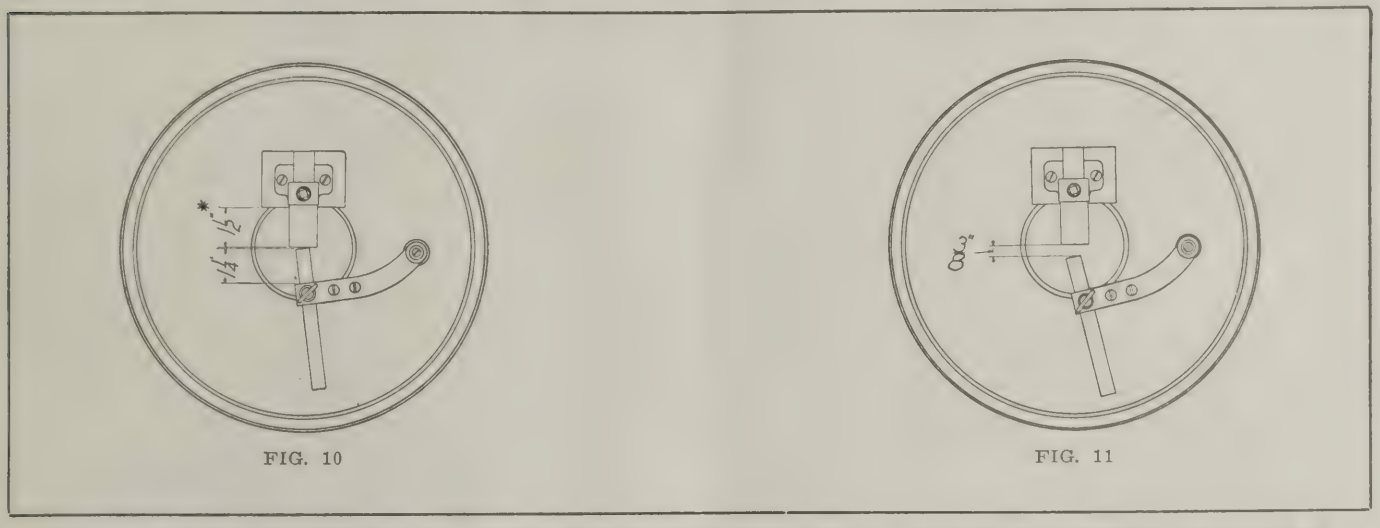

FIG. 10

FIG. 11

FIG. 10. ELECTRODE SETTING OF LUMINOUS ARC HEADLIGHT. FIG. 11. SHOWS ARC LENGTH OF LUMINOUS ARC HEADLIGHT

When the current is off, the two carbons are together. At the instant the current is switched on, the magnet coil is energized and lifts the upper carbon $\frac{3}{16}$ to $\frac{1}{4}$ in., thereby striking an arc between it and the lower carbon. The position of the lower electrode is fixed. Natural circuit interruptions, such as circuit breakers, sectionalizing switches, etc., cause the headlight to feed often enough to prevent the arc from becoming too long. If the headlight is left burning when the locomotive is standing still, the circuit should be broken at least once in 30 min. As the carbon burns away, the position of the arc changes—that is, it burns down out of focus. After about two hours' burning, the headlight should be refocused by turning the thumb wheel *B*. This should be done only when the current is turned off, because when the current is on the upper carbon is held up, and moving the lower carbon only increases or decreases the length of the arc.

A trimming gage (Fig. 18) is shipped with each headlight. This is to be used in properly focusing the arc. For this operation the upper carbon is removed and the trimming gage put in the holder until the shoulder rests against the top of the carbon-holder. The

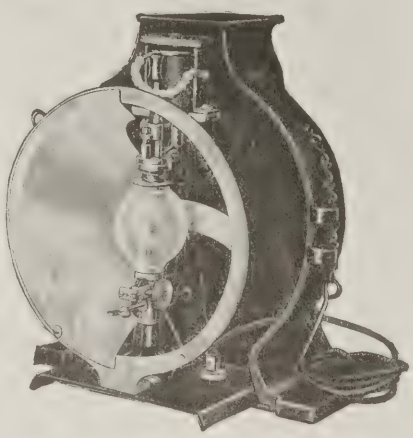

FIG. 12

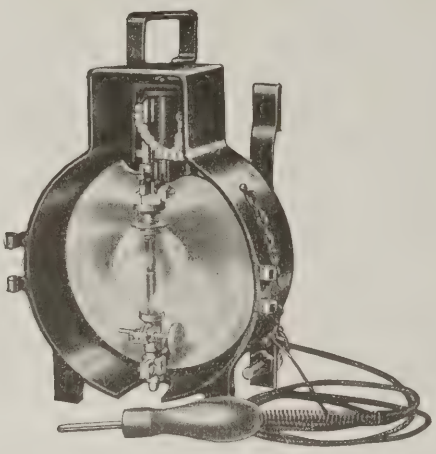

FIG. 13

FIGS. 12 AND 13. TWO TYPES OF CARBON ARC HEADLIGHTS

lower carbon should then be moved up until its top strikes the bottom of the trimming gage. After a little practice, however, the arc may be focused by the eye; that is, by simply moving the lower carbon until the narrowest obtainable beam of light is thrown down the track.

In all carbon arc headlights the upper carbon is positive and should be kept so. The headlight is so adjusted that when the arc is struck the tip of the upper positive carbon is at the focal point of the reflector. For the most part, the light of the carbon arc comes from the crater of the positive carbon, the actual light distribution being as follows: Upper (positive) carbon, 70 per cent.; lower (negative) carbon, 25 per cent.; arc stream, 5 per cent. If the polarity of the arc were reversed and the upper carbon made the negative side of the line, the arc would be out of focus.

In all carbon arc headlights the carbons may be renewed or adjusted without disturbing the globe, and, with the exception of Types V and VR, each headlight has its entire mechanism mounted on a frame which slides out of the headlight casing. These sliding mechanisms are moved forward a little for trimming. The stub of the upper carbon *G* (Figs. 16 and 17) is taken out of the top of its holder by simply lifting it. The lower carbon *H* is removed by turning the thumb wheel *B*. The lower carbon should be inserted first and adjusted to its proper position; the trimming gage shown in Fig. 18 should be used at this point, and should be put in the upper carbon-holder and the lower carbon moved up until its tip touches the bottom of the gage. Then the upper carbon should be inserted and the flexible conductor *F* slipped over its top. This flexible conductor should always be used as it insures positive electrical contact at all times. The use of this flexible conductor is necessary because no dependence can be placed on the sliding contact between the carbon and its holder. When the flexible cable is used there can be no arcing between the carbon and holder. This flexible cable must not dangle loosely against the reflector, since the cable is the positive and the reflector the negative side of the line. In Types V and VR headlights the mechanism is permanently attached to the back of the casing and therefore will not slide out. In these headlights both the upper and lower carbons are removed through the lower carbon-holder. Both carbons are released quickly by pulling outward on the shaft *K* of the thumb wheel *B* (Figs. 16 and 17). In renewing the carbons, the upper one should be put in first and moved up by turning the thumb wheel *B* until its top enters the upper carbon-holder, and then the lower should be put in. The lower one will raise the upper carbon to its proper position. In all headlights in which the carbons are vertical, the stub of the consumed carbon is the right length to be used as the lower carbon for the new trim.

In order to remove the globe *E* for cleaning, it is only necessary to lift the globe cap *I* against its spring and move the lower end of the globe forward. The carbons

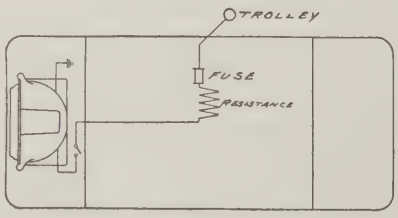

FIG. 14

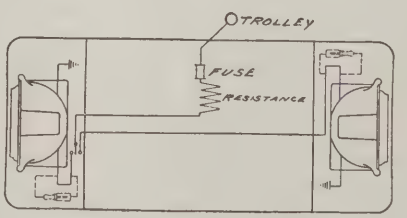

FIG. 15

FIGS. 14 AND 15. DIAGRAMS OF CONNECTIONS EMPLOYED WITH CARBON ARC HEADLIGHTS
Fig. 14—Wiring diagram for headlight with single-end equipment. Fig. 15—Wiring diagram for headlights with double-end equipment

must be removed before taking out the globe. In replacing the globe, be sure that it fits true on its seat, so as to exclude air. The top and bottom openings of the globe are parallel ground faces and seat against machined surfaces. The headlight should not be operated without a globe or with a broken globe; to do so shortens the life of the carbons.

It is occasionally necessary to polish the reflector, and this should be done carefully. If a cotton buffing wheel is available, use it; if not, the reflector may be buffed by hand. First, dust it out lightly with cotton waste and then rub with clean chamois skin. The lint side of canton flannel may be used. Always rub a reflector radially from the outer edge toward the center.

The incandescent headlight possesses the advantage of extreme simplicity and steadiness, and, in the smaller sizes, the maintenance cost is somewhat less than that of arc headlights, though if a large incandescent lamp is used which gives an illumination comparable with a good arc headlight, the item of expense for lamp renewals is apt to be considerably greater than the entire maintenance expense of an arc headlight. As mentioned before, an incandescent lamp, whether it is used in a headlight or not, is highly susceptible to fluctuations in potential, since the illumination varies as about the cube of the voltage.

The incandescent headlight is considerably more fragile than the arc headlight, and the constant vibration to which incandescent lamps are subjected in actual service makes them uncertain for mining work.

The question of voltage variation of the trolley is one which governs to a certain extent the selection of a headlight. Arc headlights operate much more satisfactorily under wide variations than do incandescent headlights. It is not uncommon for an arc headlight to operate satisfactorily on trolley circuits varying from 675 to 250 volts where the average is 550. This means that the headlight will withstand about 25 per cent. over-voltage and will operate on 45 per cent. of normal voltage. The reduction in candlepower of the arc is about proportional to the 1.5 power of the reduction in voltage. The incandescent headlight will not withstand as wide a variation in potential as will the arc.

Every incandescent lamp has a label on which its proper voltage and wattage are indicated, and to secure the best results from every standpoint it should be operated at this rating. In mining work it is impossible to operate the incandescent lamp at its labeled voltage all the time, owing to the wide variations in trolley potential, but the average voltage conditions should be determined and the headlight lamp and its resistance should be designed for this pressure. If there is a wide

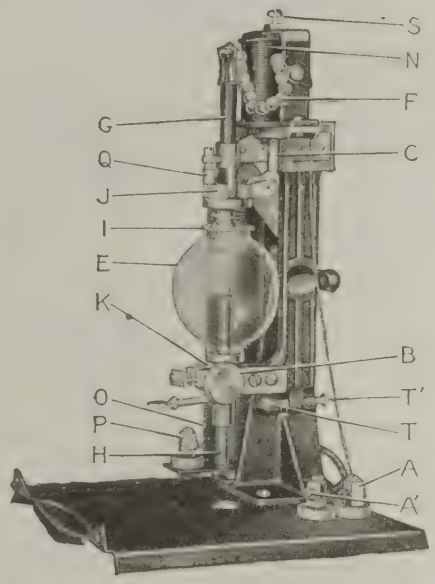

FIG. 16

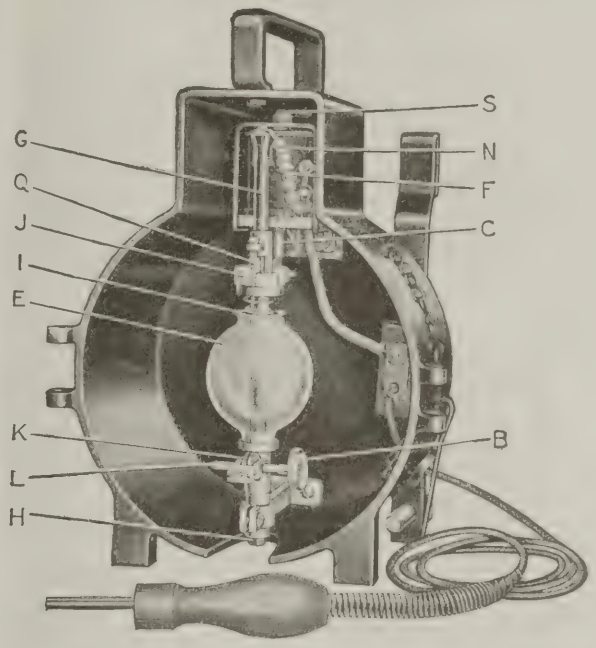

FIG. 17

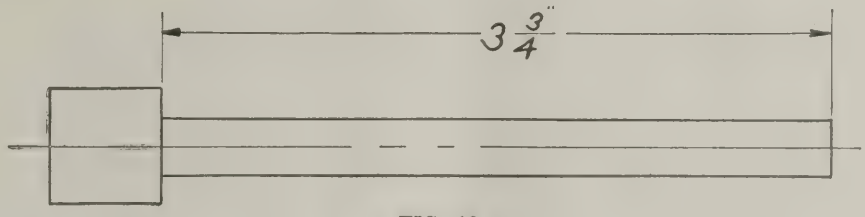

FIG. 18

FIGS. 16 AND 17. MECHANICAL DETAILS OF CARBON ARC HEADLIGHTS. FIG. 18 SHOWS TRIMMING GAGE USED FOR FOCUSING THE ARC

FIG. 19

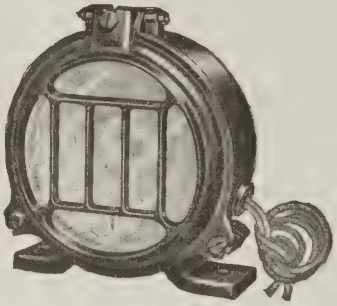

FIG. 20

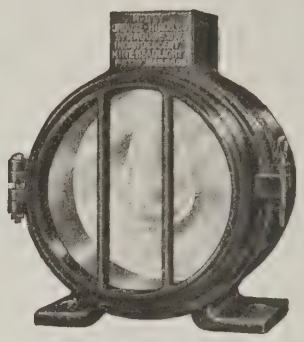

FIG. 21

FIGS. 19 TO 21. VARIOUS TYPES OF INCANDESCENT HEADLIGHTS

difference between the average and the maximum line voltage the lamp must be operated nearer the maximum, say within 5 per cent. of the maximum. If the lamp is operated below the normal voltage the amount of light will be greatly reduced, as shown in the accompanying curve (Fig. 22)[1], which emphasizes the necessity of burning the lamp at its proper voltage if the lamp is to give its rated light. Fig. 23 shows the variation in candlepower of an arc headlight with variation of arc current. The arc is considerably less susceptible to changes in current.

On the other hand, operating incandescent lamps at any voltage above the normal is detrimental. Overvoltage increases the efficiency of the lamp but reduces its life considerably, and too high a percentage of overvoltage will burn out the lamp filament entirely. This is particularly true of Mazda C lamps.

A great many different kinds of reflectors are used in headlights and a discussion of their relative merits may be of value. From a standpoint of efficiency for light projection, the following tabulation is given; the reflector with the highest coefficient of reflection is placed at the top of the list.

	Coefficient of Reflection,* Per Cent.
1. Silver plated copper	90
2. Clear plate glass mirror	83
3. Canary glass mirror	79
4. Polished aluminum	67
5. Nickel plated copper	64

*W. F. Little. Electrical Testing Laboratories.

The coefficient of reflection, however, is not the only thing to be considered in selecting a reflector, and the following list is given based upon the permanency of the reflecting surface:

1. Clear glass and canary glass.
2. Nickel plated copper.
3. Polished aluminum.
4. Silver plated copper.

As is perfectly natural, these various reflectors have a different initial cost and the third arrangement is given based upon this item, the lowest in cost being placed first:

1. Polished aluminum.
2. Nickel plated copper.
3. Silver plated copper.
4. Clear glass.
5. Canary glass.

[1]Curve taken from Bulletin of National Lamp Works.

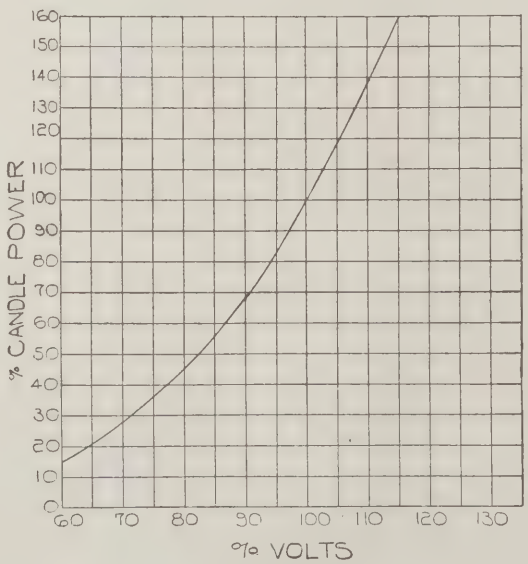

FIG. 22

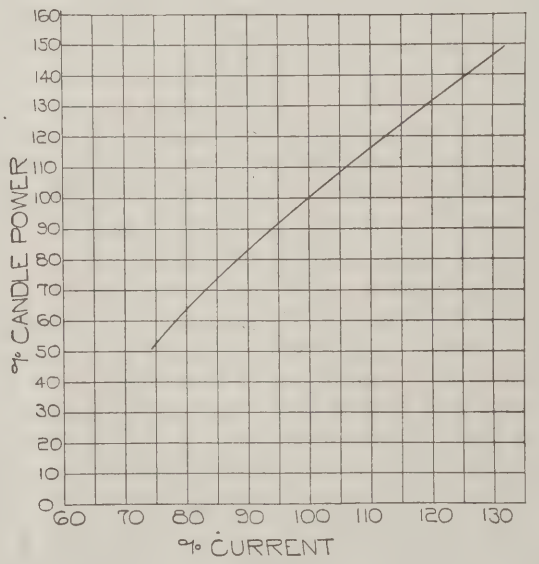

FIG. 23

FIG. 22. VOLTAGE-CANDLEPOWER CURVE OF INCANDESCENT LAMP. FIG. 23 SHOWS CANDLEPOWER-CURRENT CURVE OF LUMINOUS ARC HEADLIGHT

As has been set forth, there are three different light sources which are used in various headlights—the luminous arc, the carbon arc and the incandescent lamp. Without going into the theory of the arc formation, the light emitted by the luminous arc comes almost entirely from the arc stream. Since this is the case, larger diameter, long-life electrodes are used which are kept reasonably cool during the operation of the arc. In the carbon arc, at least 95 per cent. of the light emitted comes from the heated carbon tips, and by far the largest stream itself must be kept small and in the carbon arcs, the positive carbon tip must be kept small since this tip is placed at the focal point of the reflector.

In all headlights it is of the utmost importance that the primary light source shall be located as near the focal point of the reflector as possible. To illustrate the necessity of accurate focusing, a test was made using a 6-volt, 36-watt, focus-type Mazda lamp in a 16-in. diameter, 3-in. focus reflector. With the lamp $\frac{1}{16}$ in. ahead of the focal point, the intensity of the beam was

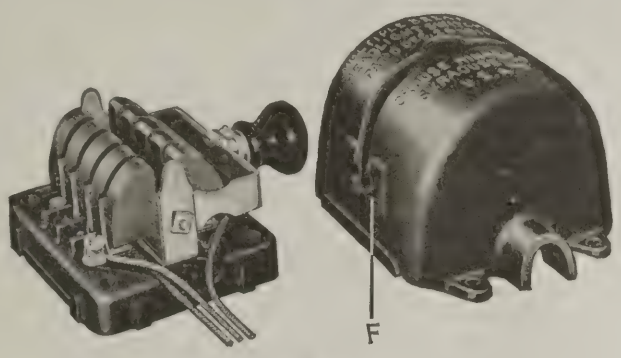

FIG. 24

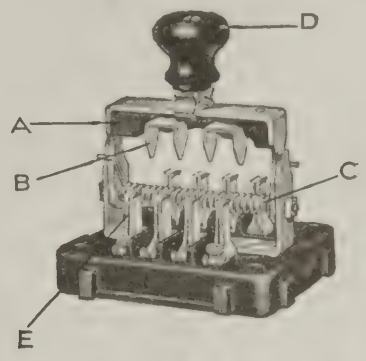

FIG. 25

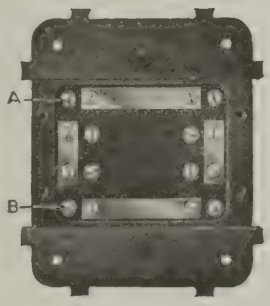

FIG. 26

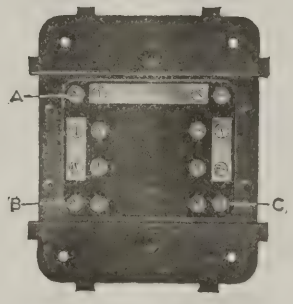

FIG. 27

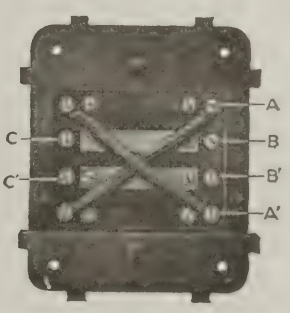

FIG. 28

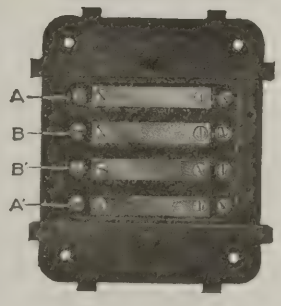

FIG. 29

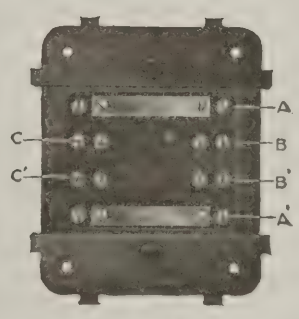

FIG. 30

FIGS. 24 TO 30. DETAILS OF VARIOUS TYPES OF MULTIPLE BREAK SWITCHES

percentage of the light comes from the white hot crater of the upper positive carbon. For this reason carbons of small diameter are used that they may be heated to a high intensity. With an incandescent lamp, all of the light comes from the incandescent filament and therefore the filament must be wound in as small a space as possible so that the angle of divergence of the beam may be only a few degrees. With a given reflecting or refracting medium, the volume of the light source determines the shape or rather the angle of divergence of the beam. In luminous arcs, this means that the arc reduced to 54 per cent. of the original intensity; $\frac{1}{8}$ in. ahead of the focal point, the intensity was reduced to 34 per cent. and $\frac{1}{4}$ in. ahead the intensity was only 6 per cent. of what it would have been if the filament were located at the exact focal point. The foregoing emphasizes strongly the necessity of accurate focusing of the light source. The light source in question was extremely small. In ordinary work it is impracticable to use light sources of these small dimensions; so the case cited above is somewhat exaggerated, but it serves

(*Continued on page 1079*)

Some Characteristics of American Coals in Byproduct Coking Practice—I*

By F. W. SPERR, JR.
Chief Chemist, The Koppers Co., Pittsburgh, Penn.

SYNOPSIS — *The products of the byproduct coke oven have a varying importance depending on the location of the oven plant and the demands of the times. At present coke is vital to the iron and steel industry; its byproducts are considered indispensable to the conduct of modern warfare. It would be difficult to do without coal tar derivatives and gas is valuable for light, heat and power. The striking power of a nation may be measured by its byproduct coke plants and its deposits of coal and iron. These and other facts are commented upon in a most interesting way by the author in the following article.*

BEFORE taking up the more technical phase of the subject it may not be amiss to discuss some of the broader relations of the American byproduct coke industry. The bulk of our material civilization during the past century has been built up by iron and energized by coal. These two are linked by coke. Next to the substitution of the shaft furnace for the old forge or bloomary, the greatest improvement in the iron industry was the substitution of coke for charcoal. It is difficult to realize that this important step was taken, with many misgivings, less than two centuries ago in England and less than 70 years ago in America. It was between 1730 and 1735 that Abraham Darby[1]—after six sleepless night, it is related—succeeded in making the first cast of iron from a coke-fed furnace in England. Other sporadic efforts had undoubtedly been made previous to that time, but it was then that a continuous development of the coke industry in England may be said to have started. On the continent of Europe the regular use of coke was not introduced until a number of years later, while in America it was not until 1850[2] that it began to exert an appreciable influence upon the manufacture of pig iron. In 1849 there was not a single coke furnace in blast in this country. Immediately after the Civil War, however, the demand for coke underwent a phenomenal development, at a rate which shows no signs of slackening. The coke industry is now truly regarded as an integral and vital part of the iron and steel industry. Not more than 110,000 tons[3] of coke were consumed in the production of pig iron in 1865. Twenty-five years later, in 1890, the annual consumption was about 10,000,000 tons. Fifty years later, in 1915, 36,700,000 tons of furnace coke and 1,700,000 tons of foundry coke were consumed. Last year (1917) the consumption of furnace and foundry coke was probably in excess of 50,000,000 tons. Thus in the past two years alone the industry has increased even more than in the phenomenal 25-year period preceding 1890.

Up to about 1893 the country was dependent upon beehive coke alone. Now please note that so soon after the establishment of the industry, when it had already attained an enormous growth and had so revolutionized the iron industry that coke instead of charcoal was recognized as the standard fuel for the blast furnace, even at this time men could foresee within a comparatively short period the same extinction that had virtually befallen the charcoal industry. Only a narrow range of coals can be used to make good metallurgical coke in the beehive oven. The supply of such coals was rapidly approaching exhaustion. In Belgium and Germany the exhaustion of beehive coals had begun to force the introduction of the byproduct oven, irrespective of any other economic considerations.

In a paper read a year ago, before The Franklin Institute, by C. J. Ramsburg,[4] there were brought forward three facts that are of great importance in this connection: (1) For every ton of coke made in the byproduct oven there is saved in fuel value alone the equivalent of 825 lb. of coal. (2) For every ton of coke made in the byproduct oven and applied to blast-furnace purposes there is a direct saving of 482 lb. of coal (200 lb. wasted in beehive oven + 282 lb. saved in blast furnace, due to the superiority of byproduct coke). (3) The byproduct oven, by reason of its great flexibility of control, enables us to make good metallurgical coke from a very wide range of coals.

Vital to Iron and Steel Industry

The development of the byproduct coke oven is as vital to the modern iron and steel industry as was the substitution of coke for charcoal. For all practical purposes it has indefinitely prolonged the life of this great business, because the new reserves of coking coal that it has opened up and that are actually in sight are far more than sufficient to take care of the estimated iron ore resources of the world.

The phase of any industry that vitally interests us nowadays is its relation to winning the war. Industrially and scientifically, only those subjects that have a bearing on this great problem should occupy our attention at this time. Let us consider this aspect of the byproduct coke industry. The vital connection of its main product—coke—with the iron and steel industry would alone suffice to place it in the front rank of the "essentials"; but, more than this, its byproducts are recognized as being indispensable to the conduct of modern warfare. One need only mention ammonia, the indispensable source of ammonium nitrate and the potential source of nitric acid; benzene; phenol; picric acid; napthalene with its mono-nitro derivative; cresol for antiseptic surgery; and, finally, toluene and trinitrotoluene, which is veritably the super-necessity of up-

[4]"Journal Franklin Institute," Vol. 183, 1917, p. 391. Reprinted in a series of articles in the Apr. 27 and May 4 and 11, 1918, issues of "Coal Age" under title of "Byproduct Coke and Coking Operations," by C. J. Ramsburg and F. W. Sperr, Jr.

to-date artillery. Besides these, there are a host of coal-tar derivatives, employed for military and surgical purposes, which it would be very difficult to do without. The byproduct coke oven is by far the largest source of these materials. Its relation to our toluene supply is of particular concern. Trinitrotoluene (TNT), which can only be produced from toluene, is the only known high explosive that combines the merits of safety, reliability and extraordinary power with the requisite capability of large-scale production. Notwithstanding the fact that we have one or two other large sources of toluene, it is unquestionably true that the byproduct coke oven is by far the most important producer. Moreover, it is the one and only source that can be absolutely depended upon to make toluene of the highest purity—especially in respect to freedom from paraffins.

All the facts, when carefully studied, justify the assertion that the byproduct coke industry is one of the most vital to the winning of the war. So essential is this industry to the conduct of modern warfare that the striking power of each nation may, to a great extent, be measured by its supply of the byproducts of coke. The extent of German preparation and advantage in this respect warrants our earnest consideration.

Hard to Obtain Reliable Statistics

It is difficult to obtain trustworthy statistics as to the actual amount of byproduct coke made in the various countries of the world. Fortunately, however, we have very reliable figures[5] for ammonium sulphate. Such figures as have been tabulated for the production of this material from coke ovens may be taken as an index to the extent of byproduct recovery practiced in each country.

In 1907 Germany produced 282,700 tons of ammonium sulphate from byproduct coke ovens. This was more than the production from the same source in all other countries combined. In the same year the United States produced 68,970 tons of ammonium sulphate from byproduct coke ovens. In 1913 the German industry produced 523,114 tons, which exceeded by over 100,000 tons the combined production of the coke ovens of the United States, England, France, Belgium and Holland. The seizure of Belgium and northern France probably gave the Central Powers an advantage in coke-oven resources equivalent to an annual production of 100,000 tons of ammonium sulphate more than the combined production of the Entente Allies plus all the neutral countries of the world. Roughly, this advantage is equivalent to the product of coking 10,000,000 tons of coal. The military significance of these figures is not difficult to realize.

The fact that in the short space of three years great steps have been taken toward equalizing this advantage is an everlasting credit to American enterprise. The year 1917 showed a gain of more than 10,000,000 tons of byproduct coke over the year 1914, which is probably equivalent to an increase of 14,000,000 tons of coal used in byproduct ovens. Ovens now under construction have an additional capacity of over 10,000,000 tons of coal per annum.

Even under the most favorable conditions, however, the American production of byproduct coke in 1918 will be less than the German production at the beginning of the war. The total German production for 1912 was about 32,000,000 and for 1913 about 35,000,000 tons, while the United States produced 22,000,000 tons in 1917 and will probably produce 27,000,000 tons in 1918. When it is recalled that we are still making beehive coke at the rate of 33,000,000 tons per year—nearly as much as the entire German production in 1913—it will be seen that there is still much work to be done.

In fact, it must be admitted that the byproduct oven has so far accomplished little more than taking care of the natural increase of coke production in America. It is a mistake to suppose that we have really done much toward abolishing the beehive oven. The amount of beehive coke made per year has undergone no appreciable diminution since 1906.

These 33,000,000 tons of beehive coke represent the loss of the following products:

Coke	2,475,000 tons
Tar	396,000,000 gal.
Ammonium sulphate	545,000 tons
Surplus gas	300,000,000,000 cu.ft.
Benzene	82,500,000 gal.
Toluene	20,000,000 gal.

Let us consider very briefly what these figures mean. Two and one-half million tons of coke per year, which is based upon the loss in the beehive oven alone and does not take into account the large saving due to superiority of byproduct coke in metallurgical practice, would keep fifteen 450-ton blast furnaces in continuous operation, or would supply the entire foundry business of the United States and leave over three-quarters of a million tons available for domestic purposes.

Four hundred million gallons of tar would, if used for fuel purposes alone, be equivalent to 2,200,000 tons of coal. It would supply enough fuel to produce 10,000,000 tons of open-hearth steel—which would fill the total estimated yearly requirements of the United States and its allies for steel for military purposes.[6]

TABLE I. BITUMINOUS COAL RESERVES OF THE WORLD—CONTINENTS

	Million Tons—Metric
North America	2,239,693
Asia	760,098
Europe	693,162
Oceanica	133,481
Africa	45,123
South America	31,397

BITUMINOUS COAL RESERVES OF THE WORLD—COUNTRIES

	Million Tons, Metric	Equivalent to
United States	1,955,521	Virginia, Tennessee, North Carolina, South Carolina, Georgia, Alabama and Mississippi.
China	607,523	Colorado.
Germany	409,975	Missouri.
Canada	283,661	New York.
Great Britain and Ireland	178,176	Maine.
Australia	132,250	West Virginia.
Russia	86,883	Connecticut, New Jersey and Delaware.
India	76,399	Massachusetts and Connecticut.
South Africa	44,540	New Jersey.
Austria	40,982	New Jersey.
Columbia	27,000	Connecticut.

NOTE—Assuming the above quantities of coal to be distributed in each country in a single solid seam 6 ft. thick, the respective coal bearing area would compare as noted.

TABLE II. BITUMINOUS COAL PRODUCTION OF THE VARIOUS COUNTRIES FOR 1910

	Million Tons		Million Tons
Australia	10.0	Great Britain	264.5
New Zealand	2.23	Spain	3.55
China	14.59	France	38.57
India	12.09	Belgium	23.13
Japan	14.79	Germany	221.98
South Africa	5.5	Austria-Hungary	38.0
Canada	13.01	Italy	0.40
United States	445.81	Sweden	0.21
Mexico	2.45	Russia	24.57

Other countries . . 8.0 million tons

[5] Annual reports on sulphate of ammonia prepared by the American Coal Products Co. The original figures in the report for 1914 are given in metric tons, which are here transposed to net tons.

[6] "Iron Age," Jan. 3, 1918, p. 57—estimate for 1918.

Five hundred and forty-five thousand tons of ammonium sulphate are nearly equivalent to the entire annual production of the German Empire just prior to the war. This annual waste of valuable ammonia would furnish about 438,000 tons of nitric acid. A discussion of what this means from a military standpoint is not my purpose, but it would be of interest, in passing, to note that the estimate made previous to the war, by military authorities, for the annual nitric acid requirements of this country in case of war was 180,000 tons.

From the standpoint of food supply this is even a more serious proposition. The permanent loss every year of more than half a million tons of ammonium sulphate—one of the most important nitrogenous fertilizers—might well arouse solicitude at a time when every effort is being made to increase our crop production. By ordinary agricultural practice about 100 lb. of ammonium sulphate are used per acre of cultivated land. We are therefore burning up every year in the beehive ovens enough nitrogen to fertilize 11,000,000 acres. It has been thoroughly demonstrated that the application of 100 lb. of ammonium sulphate to an acre of average wheat land (producing normally, say, 20 bu.) will increase the yield by about 8 bu. Our wasted fertilizer would therefore be capable of increasing our wheat production by 87,000,000 bu. a year without additional labor.

Natural Gas Supply Diminishing

Three hundred billion cubic feet of gas are nearly equivalent to the amount of natural gas consumed for industrial purposes in the states of Pennsylvania, Ohio and West Virginia, which are the three largest consumers of natural gas in the Union. The diminution of the natural gas supply is a matter of grave concern in many important industrial centers, and byproduct coke-oven gas is undoubtedly one of the most promising sources of relief. The same piping and appliances now used for natural gas can with insignificant changes be used for coke-oven gas, and the great benefit that would result from obviating the radical and expensive alterations of equipment otherwise necessary hardly needs to be pointed out. A value of 8c. per thousand cubic feet for the coke-oven gas is a conservative figure from a natural gas standpoint, and would make the loss amount to $24,000,000 a year for this product alone.

Eighty-two million gallons of benzene would be of great value in replacing or supplementing gasoline as a special motor fuel for military purposes, to say nothing of its application to making picric acid, an important high explosive. One hundred gallons of benzene are equivalent, in efficiency, to 115 gallons of gasoline; for any sort of military vehicle of limited fuel-carrying capacity this is an important fact. Eighty-two million gallons of benzene would, if used for such purposes, effect a saving of about 12,000,000 gallons of gasoline. Twenty million gallons of toluene would furnish enough TNT to make 100,000,000 three-inch shells—quite a formidable argument.

Military values are what count nowadays, and one cannot estimate military values in terms of dollars and cents. Yet, for the sake of completeness, we may sum up this situation in terms of very conservative money values under normal conditions (Table III).

It is important to realize that this annual sum total of nearly $100,000,000 worth of the country's natural resources is not merely going unutilized every year, but is absolutely destroyed—gone without the slightest possibility of recovery. It exceeds the value at the ovens of all the coke made in the United States in 1914. In comparison with this gigantic waste, the cost of replacing the antiquated beehive with modern byproduct recovery apparatus sinks into insignificance; even at present prices the replacement could be accomplished for less than $300,000,000. The war is costing the United States about $30,000,000 per day. This rate of expenditure would pay for the abolition of every American beehive oven in ten days.

TABLE III. MONEY VALUE OF COKE BYPRODUCTS

2,475,000 tons coke at $3.80	$9,405,000
396,000,000 gal. tar at 3½c	13,860,000
545,000 tons ammonium sulphate at $60	32,700,000
300,000,000 M. cu.ft. gas at 8c	24,000,000
102,500,000 gal. motor fuel [7] at 15c	15,375,000
Total	$95,340,000

Perhaps we are departing too far from the scope of what was intended to be a technical paper, but this phase of the subject is one that vitally concerns all of us at the present moment, and every possible agency should be interested and engaged in accelerating the change of the industry to the modern basis. The principal—and probably the only important deterring—factors are the present high cost of material and labor and the difficulty, under present conditions, of financing the expensive plants required. There is a rather strong temptation—which must be thoroughly understood and guarded against—to resort to cheaper forms of construction that have been tried and found wanting in the past, and which, if yielded to, will only discourage and delay the complete establishment of the industry. It would seem that the Government might well assist in furnishing or reinforcing the capital necessary for a wholesale and immediate eradication of the beehive oven. The immediate practical, military benefits would be a sufficient argument, aside from the permanent conservation and the assured stability of the industry. Any development that can increase our wheat crop by nearly 90,000,000 bu. per year, that can more than double our material for high explosives, that is absolutely necessary in order to insure to America and its allies an unquestioned superiority in modern munitions, should be encouraged and hastened with every possible facility.

TABLE IV. CONSUMPTION OF COAL AND LIGNITE IN THE UNITED STATES IN 1915

(M. R. Campbell, U. S. Geological Survey, Professional Paper 100-A.)

	Net Tons	Per Cent. of Total
Railroad fuel	122,000,000	28
Steamship fuel	10,700,000	2.3
Beehive coke	42,300,000	9.3
Byproduct coke	19,500,000	4.3
Coal gas	4,600,000	1.0
Domestic and small steam trade	71,300,000	16.0
Industrial steam trade	143,800,000	33.0
Exported	18,800,000	4.0
Used at mines	9,800,000	2.0
Special uses	700,000	0.1
Total	443,500,000	100.0

Nor must it be forgotten that the beehive is not the only spendthrift of the important byproducts of coal. The householder who burns a hundred tons of Pittsburgh coal in the winter months is likely, while standing aghast at the "crime of the beehive oven," to forget that he himself is accessory in what is in the aggregate a greater crime. Table IV, compiled from the sta-

[7] Including only benzene and toluene. If all the available light oil constituents were included we would have at least 120,000,000 gal. motor fuel.

tistics of the United States Geological Survey for the year 1915, shows the distribution of the coal produced in the United States.

Every encouragement should be given to the use of coke, gas, and briquetted fuel, which not only are important in national conservation, but are intrinsically cleaner, more economical and more convenient.

All such considerations, vital as they may seem to the needs of the present moment, are in a larger sense dwarfed by the significance of America's enormous preponderance in reserves of coking coals. These are such as to insure the stability and normal growth of the industry for many centuries in a sense that is true for no other country. The statistics given in Table I were taken from the elaborate report of the Twelfth International Geological Congress on the Coal Resources of the World.

The figures for bituminous coal may be taken as a comparative index of the reserves available for making coke. It is the byproduct oven that makes this broad generalization possible. Consider, with these statistics, the supplementary figures in Table V for the principal iron reserves of the world, compiled by Edwin C. Eckel.[8]

TABLE V. PRINCIPAL IRON ORE RESERVES OF THE WORLD

United States	Minimum	Maximum
Lake Superior region	2,000,000,000	2,500,000,000
Southern red ores	1,500,000,000	2,000,000,000
Texas brown ores	600,000,000	1,000,000,000
Other Southern ores	500,000,000	750,000,000
Northeastern States	300,000,000	600,000,000
Western States	300,000,000	700,000,000
Total United States	5,200,000,000	7,550,000,000

Continent	Actual Ore Tonnage	Equivalent Tons Metallic Ore
North America	14,710,000,000	6,455,000,000
South America	8,000,000,000	5,000,000,000
Europe	12,032,000,000	4,733,000,000
Total	34,742,000,000	16,188,000,000

It needs no prophetic imagination to foresee that the future of the vast industries that are based on these two materials must largely rest with America, and her duty to conserve such resources becomes more than a local necessity; it is an international obligation.

It may be of interest to survey the present distribution of the byproduct coke industry in America, and the way in which the various coal fields are being utilized.

Byproduct coke is now being made in the following states: Massachusetts, New York, New Jersey, Pennsylvania, Maryland, West Virginia, Alabama, Kentucky, Michigan, Indiana, Illinois, Wisconsin, Missouri, Minnesota, Tennessee and Washington. Plants are also being built by The Koppers Co. in Colorado and Rhode Island —eighteen states in all. Of these, only six—Alabama, Colorado, Ohio, Pennsylvania, Tennessee and West Virginia—were coke producers of magnitude before the advent of the byproduct oven. Together with this tendency to distribution, there is also an effort of concentration which is important. The effect in transplanting the business of coke manufacture from more or less secluded mining districts to important industrial centers is very marked. Two-thirds of the byproduct coke producing capacity of the United States (including ovens under construction) is located within two hours' ride of one or another of five large cities: Chicago, Pittsburgh, Cleveland, Detroit and Birmingham. The amount of byproduct coke capacity in these five metropolitan districts exceeds the total coke (beehive and byproduct) made in the United States in 1900.

[8] "Iron Trade Review," Jan. 15, 1914.

The intensive concentration of plant capacity made possible by the byproduct coke oven is especially noteworthy. A striking example is the plant being built by The Koppers Co. for the Carnegie Steel Co. at Clairton, Penn. This plant, the largest in the world, will soon be put into operation with 640 ovens, having a capacity of 4,000,000 tons of coal per year. The plans provide for an extension of this plant to a total of 24 batteries of 64 ovens each. Some data as to the capacity and production of such a plant are as follows:

ANNUAL CAPACITY OF 1,536 OVENS

Coal	9,600,000 tons
Coke	6,720,000 tons
Tar	80,640,000 gal.
Ammonium sulphate	110,880 tons
Surplus gas	60,480,000,000 cu ft.
Benzene	16,800,000 gal.
Toluene	4,032,000 gal.

This great plant, when completed, will have a coking capacity equivalent to 11,200 beehive ovens (one 12-ft. beehive oven producing 600 tons of coke per year). In ordinary double-row construction (120 beehive ovens to a block 900 ft. long) this would make 16 miles of beehive ovens. The byproduct plant, including some vacant space, is only 1500 yd. long and 1200 yd. wide.

(*To be continued*)

Purification of Coal Gas by Electricity

By M. Meredith
Liverpool, England

The deposition of tar and other impurities from coal gas by electrical means has recently been undertaken and satisfactory results have been attained. High-tension direct current is discharged between a cage made of thin wires and a tube, the system of wires being mounted in the middle of the tube. It is essential to prevent access of air to the precipitation chamber in order to avoid the danger of explosion. It was found that the tendency toward the production of harmful discharges is least if the wire electrode is negative. The shape of the electrode is highly important, and the sustaining insulators are specially formed and cemented into the tube. A ½-in. gas tube is passed through a series of cast-iron disks, between which the thin steel wires are fixed. The whole is then placed in a felt-covered tube, which constitutes the grounded electrode.

The apparatus was tested with a flow of 265,000 cu.ft. of gas per hour, two precipitation chambers 4 ft. 11 in. in height and 8 in. in diameter being used. Disks of the active electrode were 4 in. in diameter, and were covered with 16 thin piano-steel wires. The passage traversed by the gas was 12 ft. 4 in. long. The gas was exposed to the electrical discharge for 0.4 second.

After five hours' operation the tar deposited on the insulators was found to interfere with the action. For complete cleansing of the gas 0.2 kw.-hr. was required for each 265,000 cu.ft. The total cost of the apparatus was about $500. The test was made with 20,000 volts and a current of about 3 milliamperes.

The temperature of the coal gas has little influence on the operation. Tar deposited at 175 deg. F. is free from water and suitable for asphalting. It can be cleansed in a washing apparatus and the residue of naphthalene can be reclaimed by a second electric precipitation. The illuminating and heating capacity of the gas is improved if the tar is removed while hot.

Dewatering Pits for Washed Coal

THE Cambria Steel Co., of Johnstown, Penn., after much investigation of washed coal dewatering devices and methods, and 14 years of experience with dewatering pits at its Franklin washery and coke-oven plant, has adopted dewatering pits for washed coal at the Rosedale washery and coke-oven plant now under construction. The succeeding description of dewatering pits elucidates the most important features that should govern adoption.

The attractive features of dewatering pits are: (1) A drained washed coal containing 8 to 9 per cent. moisture; (2) a filtered water free from sediment, for recirculation; (3) no escape of dirty water (to pollute private and public streams) except that small amount evaporating and adhering as external moisture to the coal; (4) a rapid filtration of the water so as to gain a brimful pit of coal, without shifting the stream of water and coal from the washing machines; (5) uniformity of the drained mass of coal, in regard to fine and coarse sizes, sludge and pieces of various characteristics being evenly distributed so that a homogeneous coking coal may be gathered; (6) no mechanical power necessary to aid or hasten the dewatering of the coal; (7) permanent construction with only a minimum maintenance expense; (8) an economically operated apparatus for removing the drained coal.

The principle involved in the drainage of a pit of coal is that water moves gradually in a wavering descending motion through a mass of minute particles at rest, and is clarified during this movement. The dewatering capacity of a pit depends upon the relation between the number of square feet of filtering surface to the quantity of water delivered in a given time and the fineness of the coal.

Tests Indicate Average Filtering Capacity

Tests made at five coal washeries using dewatering pits indicate that the average filtering capacity of a pit is 32 gal. of water per hour for each square foot of filtering surface, when dewatering coal in sizes ranging from ½-in. cubes to dust, and the pit will be filled brimful of coal without temporary cessation to prevent water overflowing the pit walls. Most careful moisture determinations were also made of the drained washed coal at different times as gathered from the pits for coking after various hours of drainage, with the results shown below, the drained washed coal averaging in fineness ½-in. cubes to dust. (See Fig. 1.)

Pits 24 Ft. Deep	Average Moisture, %	Maximum Moisture, %	Minimum Moisture, %
After 24 hours' drainage	9.15	10.36	7.37
After 36 hours' drainage	9.05	10.61	7.10
After 48 hours' drainage	8.26	10.13	7.00
After 60 hours' drainage	8.05	9.74	6.84
After 72 hours' drainage	7.97	9.48	6.18

Pits 16 Ft. Deep	Average Moisture, %	Maximum Moisture, %	Minimum Moisture, %
After 12 hours' drainage	10.05	12.96	8.16
After 24 hours' drainage	8.46	9.07	8.06
After 36 hours' drainage	8.39	8.60	8.03
After 48 hours' drainage	7.90	8.31	7.76
After 60 hours' drainage	7.65	8.00	6.85
After 72 hours' drainage	7.60	7.79	6.90

The pits are formed by rectangular concrete walls of a thickness suitable to withstand the pressure when the pits are filled with coal and water. The ultimate concrete bottom is laid slightly sloping toward centrally located drains which transfer the filtered water to a pump sump for repeated use. Above the ultimate bottom, leaving an intervening space of 4 in., a filtering platform is placed. This contains small V-shaped gaps for supporting the coal and allowing the passage of the dripping filtered water onto the concrete bottom. In practice the final 8 to 12 in. in depth of coal is not drawn off but remains on the filtering platform as a permanent filter bed. This bed should be stirred up frequently, say after each third filling of the pit, by the appliance provided on the traveling coal excavator, so as to present a more nearly perfect porous bed, in order that the filtering capacity of the pit may not become diminished.

The permanency of properly designed and constructed concrete pits is unquestioned. They do not deteriorate in usefulness or value by constant usage. The only renewal necessary is the replacement of the false bottom used as a filtering platform in two to four years, according to usage. This platform is built in sections of about 4 x 6 ft., so that one or more sections may be readily replaced when necessary.

Cleaned Coal Delivered by Sluiceways

The cleaned coal and black water from the washing machines is delivered directly to the pits by means of extension gravity sluiceways swung over the top of the pit so that the latter will be uniformly filled with coal. The separation of the water from the coal requires no machinery, attendance or supplies. To save the water draining from pits when the washing machines are not in operation, concrete reservoirs of sufficient capacity are provided with drains from the pits and to a pump sump, so that all water will be saved for recirculation when the washing machines are again operated. As there are no drains leading from any part of the drainage system to sewers or ditches, there is no chance to pollute streams with water holding impurities in solution or suspension.

There are no mechanical dewatering units between the washing machines and the drainage pits. The problem of sludge and dirty water disposal is thus entirely eliminated, as all fine coal and sludge is intermixed with the drained washed coal. This method of dewatering results in a great saving of water, power, labor and upkeep over the ordinary expensive dewatering methods employing centrifugal driers or perforated bucket elevators, with sludge tanks and a multiplicity of machinery. Wherever these are in use great fields of fine coal and sludge are visible with the accompanying pollution of near-by streams.

The fines to be dealt with consist of particles capable of passing through extremely fine meshes, the greater part of them being from ⅛ in. to 1/100 in. in diameter, or say, from 64 to 10,000 to the square inch.

By an act passed by the Pennsylvania Legislature in 1907, the Water Supply Commission of the state was given jurisdiction over encroachments along the streams and the dumping of solid wastes into them. This measure provides a heavy penalty and covers all streams whose

drainage areas are over ½ square mile in extent, except the tidal portion of the Delaware River and its navigable tributaries. Ultimately this law will be universally and thoroughly enforced. In Table I is shown the number of square feet of pit filtering surface necessary, when washing coal at the rate of 200 net tons per hour, with washing machines that require varying quantities of water in order to wash one net ton of raw crushed coal.

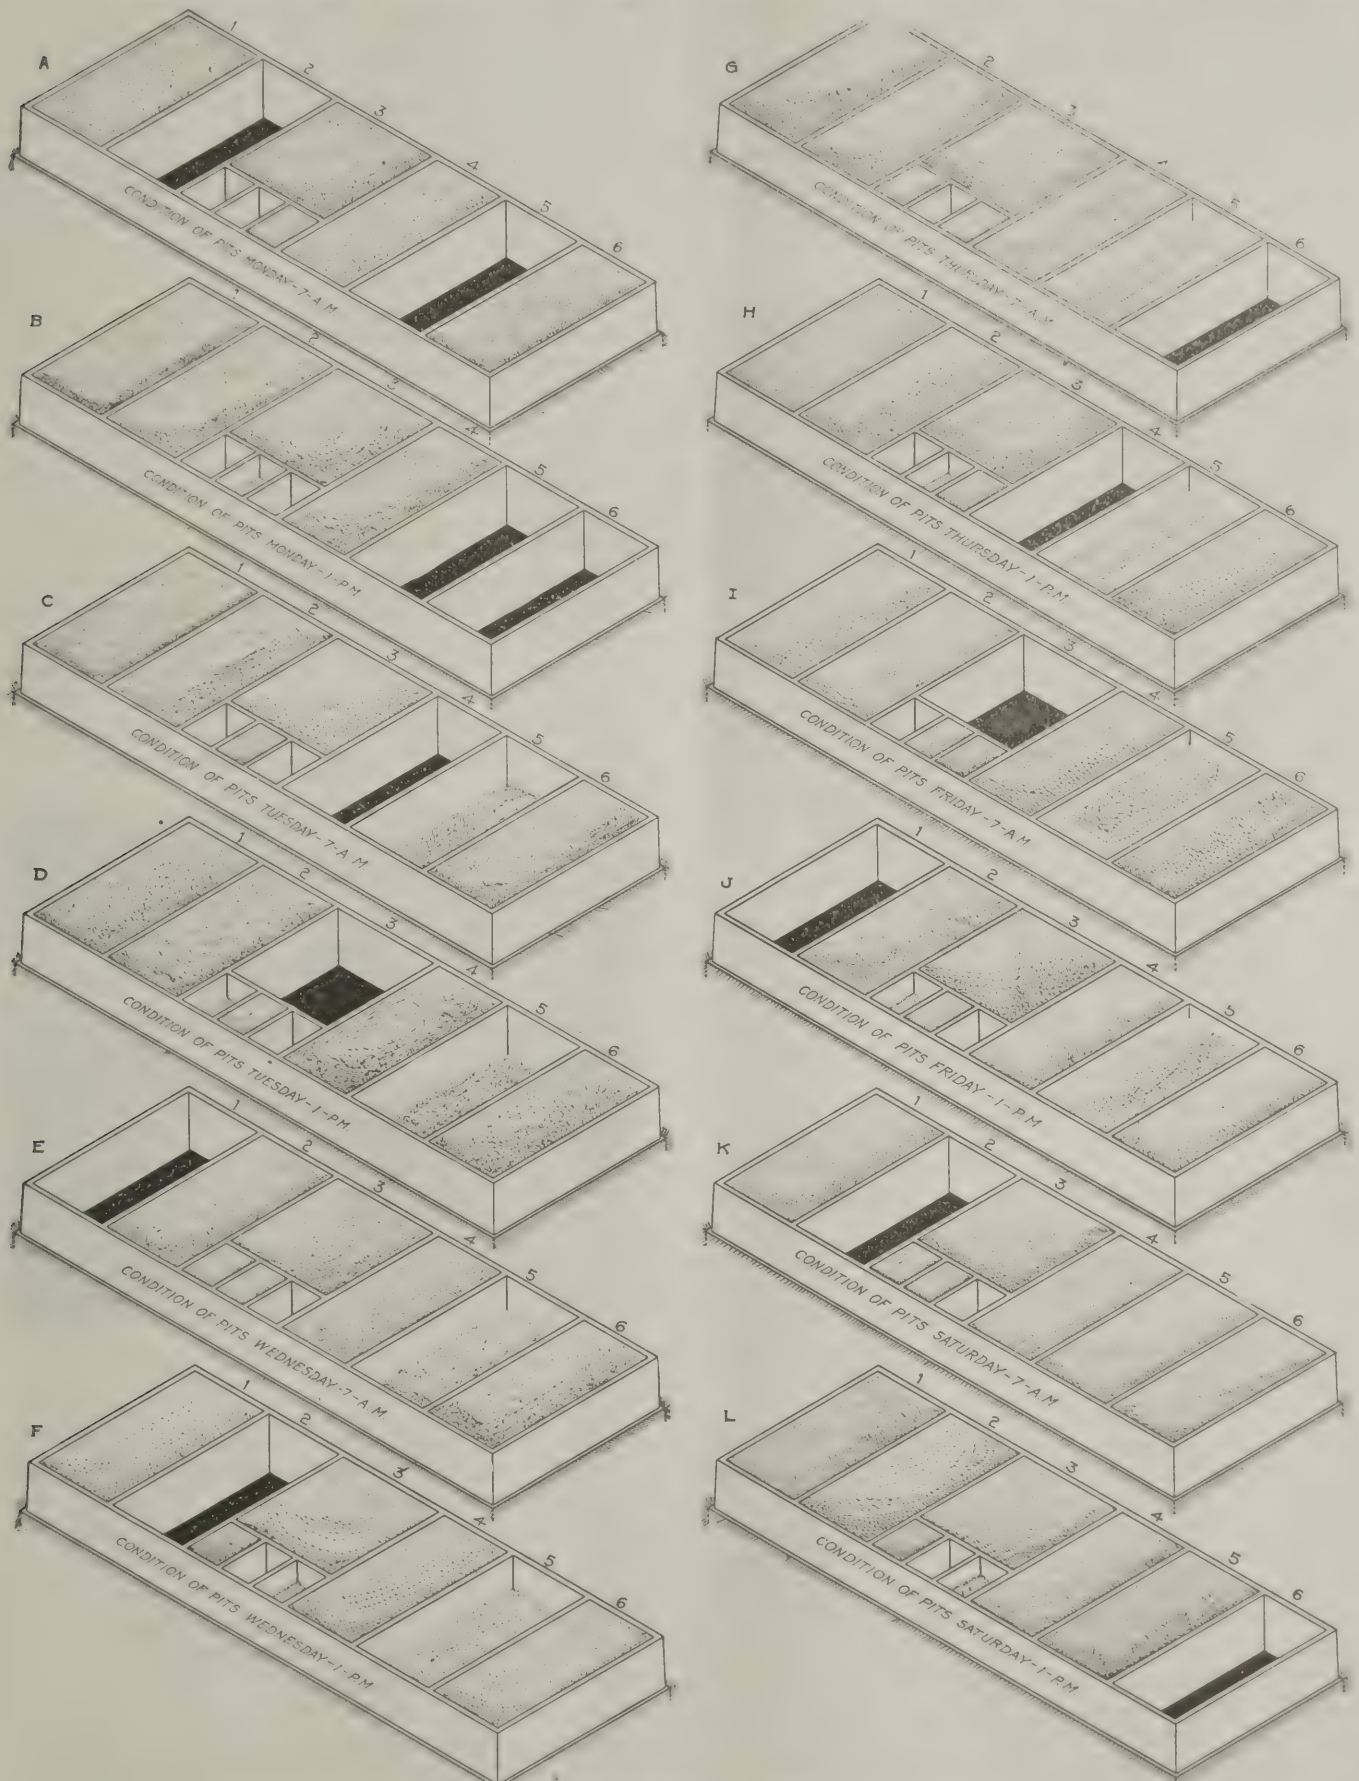

FIG. 1. ILLUSTRATING CONDITION OF WASHED COAL AND REFUSE PITS AT STATED INTERVALS

TABLE I. MOISTURE DETERMINATIONS AFTER VARIOUS HOURS OF DRAINAGE

Ratio of Water to 1 Ton of Coal	Various Quantities of Water Necessary to Wash 1 Net Ton of Crushed Raw Coal In Cu.Ft.	In Gal.	In Lb.	Net Tons of Crushed Raw Coal Washed per Hour	Square Feet of Pit Filtering Surface Necessary
1	32	240	2,000	200	1,500
1½	48	360	3,000	200	2,250
2	64	480	4,000	200	3,000
2½	80	600	5,000	200	3 750
3	96	720	6,000	200	4,500
3½	112	840	7,000	200	5,250

The ratio of water to that of coal is determined by the water requirements of the particular coal-washing machine under consideration. One washery handling 200 tons of coal per hour, adopting a specific form of

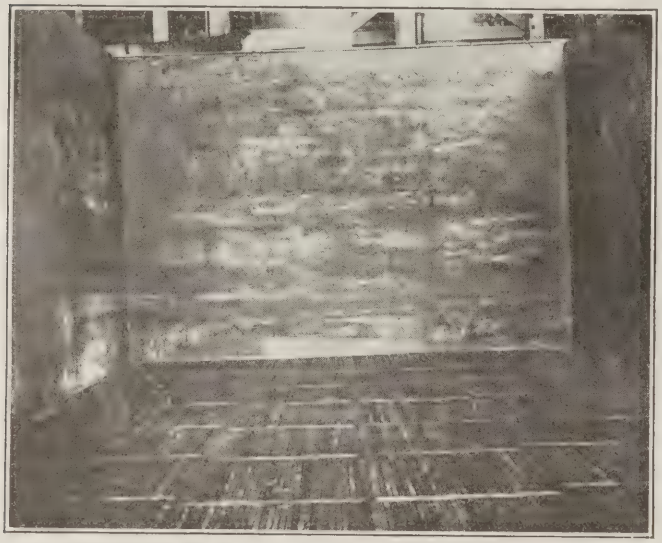

FIG. 2. DEWATERING PIT AT COAL WASHERY OF CASCADE COAL AND COKE CO., TYLER, PENN.

washing machine, may need water in the proportion of 1½ to 1 of coal, requiring only 2250 sq.ft. of pit filtering surface; while another washery handling the same tonnage per hour using another form of washing machine may need water in the proportion of 3 to 1 of coal, necessitating 4500 sq.ft. of pit filtering surface.

When considering the adoption of dewatering pits, it is important to study the water requirements of coal-washing machines and to see that a machine requiring an extravagant quantity of water is not selected, since it would demand dewatering pits of extreme and excessive dimensions. As aforementioned, the series of tests made, relating to the filtering capacity of pits, demonstrated that the drainage capacity averaged 32 gal. of filtered water discharged per hour for each square foot of filtering surface, through coal ranging from ½-in. cubes to dust.

To ascertain the floor dimensions of a pit to hold, say, 1000 net tons of drained coal, or 40,000 cu.ft., weighing on a dry basis 50 lb. per cubic foot, assuming that water will enter the pit with the coal for five consecutive hours, the coal coming at the rate of 200 tons an hour, each ton requiring 360 gal. of water for washing, the water filtering away at the rate of 32 gal. per hour for each square foot of filtering surface, the formula is as follows:

Let

a = The number of gallons of water required to wash one ton of coal;

b = Tons of coal delivered to pit per hour;

c = Gallons of water filtering away per hour, per square foot of pit surface;

x = Square feet of pit surface required.

Then $a \times b = x$.

Example—a = 360 gal. of water per ton of coal;

b = 200 tons of coal;

c = 32 gal. of water per hour per square foot of draining surface.

Then $360 \times 200 \div 32 = x$, or 2250 sq.ft. of pit floor surface required. This would be equivalent to a pit, say, 30 ft. wide by 75 ft. long.

The formula for determining the height of pit walls is as follows:

Let

d = Square feet of pit surface required;

e = Cubic feet of coal required;

x = Height of walls in feet;

$e = x$.

Example—d = 2250 sq.ft. of pit floor surface;

e = 40,000 cu.ft. of coal.

$40{,}000 \div 2250 = x$, or 17 ft. 10 in. = the height of pit walls.

To offset the 8 in. to 12 in. in depth of coal used as a filter bed and the height of filter platform above the concrete floor, about 20 in. must be added to the height of walls, to acquire a working capacity of 1000 tons of coal. This will make a pit averaging, say, 30 ft. wide, 75 ft. long and 19 ft. high above the concrete floor.

A pit to drain coal from a washery using 720 gal. or double the quantity of water assumed above as being

FIG. 3. DEWATERING PIT AT NO. 3 COLLIERY WASHERY, LACKAWANNA COAL AND COKE CO.

necessary to wash a ton of coal, would require a filtering surface of 4500 sq.ft. to receive the coal and water in five consecutive hours at the rate of 200 tons of coal per hour. This would mean a pit, say, 45 ft. wide, 100 ft. long and with a total depth of 10 feet 6 inches.

A pit this size would not be economical in ground space, construction or in handling the coal and water to and from it. Dewatering pits are not practical to operate in connection with washeries using an excessive quantity of water to wash a ton of coal.

The table showing moisture determinations after various hours of drainage indicates that after 24 hours in disturbance, additional drainage time does not reduce

the moisture content of the coal materially, the water draining off rapidly; and with the exception of a few feet at the top, no benefits of air circulation are secured to aid in reducing the moisture. The coal is so closely packed by the water action that trenches formed by slides 30 in. wide and 4 to 6 ft. deep do not cave in.

The drained coal is gathered from the pits by a crane, having a vertical and horizontal motion. This is mounted on wheels and provided with numerous buckets for excavating and elevating the coal to a belt conveying system that discharges it into larry bins for use in coking. The crane spans the pits, and its movements are guided by rails fastened to the top of the longitudinal pit walls. The elevating capacity is from 400 tons per hour up.

Referring to the illustrations, Fig. 1 indicates the condition of the washed coal and refuse pits over a six-day period. Fig. 2, which illustrates a dewatering pit at the coal washery at Tyler mine of the Cascade Coal and Coke Co., gives a good view of the filtering platform. Each pit is 30 ft. wide, 30 ft. long, 16 ft. deep, and holds 360 net tons of coal. Fig. 3, a view of the dewatering pits at the No. 3 colliery coal washery of the Lackawanna Coal and Coke Co., near Wehrum, Penn., indicates the relation betwen the dewatering pits and the crane used to reclaim the coal after drainage. Each pit is 70 ft. wide, 35 ft. long, 24 ft. deep, and holds 1500 net tons of coal. The filtering platform has been removed so as to show the concrete bottom and the drains which convey the filtered water to the pump sump for reuse.

Who's Who In Coal Mining

W. E. Deegans

Pep, punch and perseverance (not to speak of his red hair) are characteristics which have given W. E. Deegans, of Huntington, affectionately known to his friends as "Bill," his conspicuous place in the coal industry of southern West Virginia. There are few counties in that part of the state that do not have one or more companies in operation in which W. E. Deegans is interested. "Bill" Deegans has personality and magnetism, like all big and genial men. That pleasing personality, with his keen business acumen and well-balanced foresight, has enabled him to forge rapidly to the front in West Virginia's industrial life. Old man Opportunity has never managed to elude the vigilance of W. E. Deegans. When Opportunity appeared on the scene, the door was opened even before Opportunity knocked.

Only two-score years have passed since a red-headed youngster arrived with a smile in a Coal Grove, Ohio, household. When young Deegans was not attending the Lawrence County schools he was working in his father's mines. In that way he gained a pretty thorough knowledge of mining, knowledge which stood him in good stead in after years, when he began to acquire and operate coal properties.

Thurmond, in the heart of what is now the New River coal field, attracted W. E. Deegans to West Virginia before he was of age. When he was following other lines of business he ever kept one eye on the possibilities of West Virginia as a great coal-producing state, and all his surplus, when he had one, went into coal lands or was invested in coal stock. His judgment was, before long, vindicated, and in the course of a few years he found it necessary to devote his entire time to his coal properties, which have now become so numerous that they are located upon two different roads in widely scattered sections. He directs the affairs in sixteen different mining operations, some of which are: The Beckley Vein Coal Co., Cub Fork Coal Co., Deegans Eagle Coal Co., Devils Fork Coal Co., Guyan Valley Coal Co., Miller-Pocahontas Coal Co., Mullens Smokeless Coal Co., Orville Coal Co., Paragon Colliery Co., Royal

W. E. DEEGANS

Block Coal Co., Sterling Colliery Co. and the Virginian Smokeless Fuel Company.

The center of Mr. Deegans' activities are at Huntington, from which point he directs operations so far as it can be done from the office. Huntington was no doubt chosen because the Virginian, Chesapeake & Ohio and Norfolk & Western railways converge at that point, and with as many mines as he has to direct, he must have a convenient place from which to jump in any direction. It would keep any man constantly on the go, but as Bill Deegans is a veritable human dynamo, he thrives on work that would wear out any ordinary individual.

With all he has to absorb his attention, Bill Deegans nevertheless has time for his friends, and time to smile and shed happiness all around him. Busy as he is with his own affairs, he has yet found time, or made it, to engage in many war-work activities and to help in every public movement.

On the basis of four tons of bituminous coal said to be necessary on the average to produce one ton of steel products, the increased output of steel in 1916 would indicate an increased demand of 40 million tons of bituminous coal in 1916 for the steel industry.

Development Period of a Mine

By H. H. STOEK
University of Illinois, Urbana, Ill.

SYNOPSIS — *When does the operation of a mine begin? Six answers to this question are here given, and the advantages and disadvantages of each set forth. A wide diversity in opinion and practice exists, and discussion is invited.*

IN a recent article in the *Daily Digest* of the National Coal Association, W. B. Reed, accounting secretary of the association, says:

In the development of a coal mine all expenditures should be capitalized, and this course should be followed until the projected capacity of the mine is reached, the operating buildings constructed, the machinery installed, and the mine is producing, or is in a position to produce, the quantity of coal for which it was developed. During this period credit should be given to the development for the development product; that is, for the coal produced during that period.

After this point is reached and the mine settles down to a normal production, the purpose of each additional expenditure for equipment will need to be carefully weighed as to whether or not it is properly an item of expense or an additional investment of capital, a replacement of a unit worn out and demolished, or an additional unit of the same kind intended to increase production, and whether it will permanently and materially increase the output, or decrease costs; also whether it will have a salvage value because of the fact that it may be sold or transferred to another operation, when the operation for which it was purchased has been abandoned.

This, at first sight, seems very reasonable, but it by no means represents the practice of many mining companies at the present time and it may, therefore, be of interest to consider some of the methods used for determining when development charges end and when operating charges begin.

Operation Charge Should Begin Early

Accountants and writers on costkeeping generally advise that the charge for operation should begin as early as possible in the life of the operation so as not to have an unduly overloaded capital account and so that operating costs may be watched closely as soon as possible. Quite naturally the operating man tries to put into capital and overhead accounts everything possible so that his daily costs may be kept down, and he is in sympathy with anything that will apportion charges to any other account than operation and is willing to have the development charge kept open as long as possible.

To obtain uniform costs, or costs that permit a comparison to be made between different companies or different mines operating under the same company, it is not of nearly so much importance at just what point development costs cease and operating costs begin, but it is highly important for purposes of comparison that all of the companies or all of the mines should adopt the same point.

I know of the following different practices in this matter, and the advantages and disadvantages of each as I see them are given under each head noted.

1.—*Operation begins when the shaft penetrates the coal.* This is the practice of the superintendent of one division of a large coal company, but it is quite unusual and the reason for its adoption seems to have been purely a local convenience in bookkeeping in order to keep the shaft-sinking costs entirely separate from the underground operations and so that these could be definitely closed as soon as the coal was penetrated. After that time all work of opening up was kept as a distinct item and charged to operation. Whatever may be the justification in this particular instance on account of local conditions, it is not a practice that will be generally used, as it separates from the operating account a considerable expenditure that properly belongs there.

When Does Operation Really Begin?

2.—*Operation begins when the mine has reached the full daily output for which it was designed.* This is the time given by W. B. Reed in the *Daily Digest* of the National Coal Association, and while it is apparently a perfectly logical point to adopt there are arguments against it that need to be considered and are of importance. Many mines do not reach their rated capacity for many years, if ever, due to market or other conditions. Suppose, for instance, a mine is designed for an output of 5000 tons per day and all of the surface equipment needed for such an output is provided, but due to unforeseen troubles in operating, labor conditions, inadequate market, etc., it is found impossible to raise more than 4000 tons of coal per day. Such a mine under definition 2 would never be an operating unit, although it might be a regular producer of a large amount of coal and be worked at a profit.

The principle of this method is used by many companies by charging to capital account or some account such as "construction" all development charges until the mine is ready to produce the daily tonnage for which it was planned; that is, until enough entries have been driven and provision made for sufficient rooms to give the desired output if labor and trade conditions warrant it. Up to this time all the development, plant and equipment costs are charged against capital account, while all coal sold during that time is credited to that account. After the mine has been developed to the point where it can produce its rated capacity, the operating charges are begun and thereafter all expenditures are so charged unless they are intended to give a positive increase in capacity over the original plan, in which case they then become capital charges.

J. R. Findlay, in his book on "Cost of Mining," charges to capital all expenditures up to the time when the mine is producing and after that time only such expenditures are capital charges as are made to increase the capacity of the mine. This continues until the time when the mine has reached what appears to be an average production. The capital thus charged is the amount to be amortized over a reasonable period at a given interest rate. For this purpose Findlay uses a rate of 5 per cent.

3.—*Operation begins when coal is hoisted from rooms.* This method is used by a number of companies and gives a very definite point and one that marks the time when the mine is really a producing one and not merely a mine under development. It has the advantage of giving a definite point that insures uniformity among a number of mines and it is not dependent on trade, market or labor conditions.

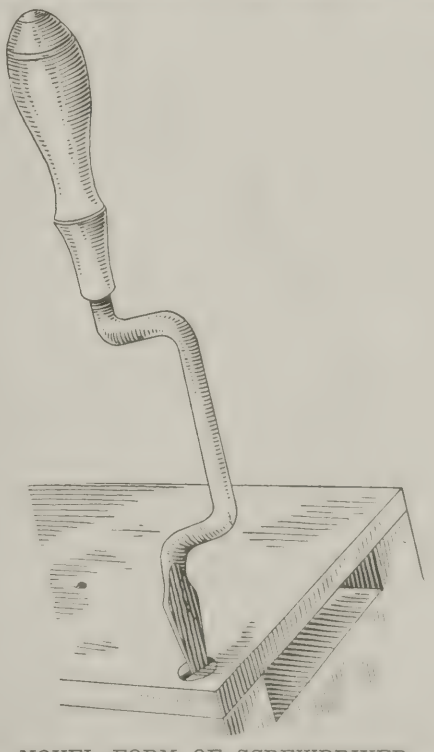
An objection to this point is that the mine may not be self-supporting or making money for some time after this point is reached, and it is not working under normal conditions until it can be said to be self-supporting. Also during the unprofitable construction and the development period it is generally considered allowable and wise to charge interest upon the capital invested and to include this as a part of the total capital that has to be amortized. If the break between capital and operating charges is made before the mine can operate at a profit, or at least without a deficit, the interest-bearing period upon capital is shortened unduly or else there is introduced an increased difficulty in accounting.

Defines the Term "Even Break"

4.—*Operation begins when an "even break" occurs.* The term "even break" as used by a number of companies in determining this point means such a time in the operation of the mine that the selling price just equals the operating cost and there is neither profit nor loss on the operation. Such a point is, of course, indefinite and depends upon trade conditions, markets, contracts, weather and many other variables, so that it is difficult or impossible to compare conditions between a number of different companies; in other words, to adopt a common standard. Such variables will, of course, be most serious in mines operating under widely different conditions or in different localities, while for a group of mines in the same district with approximately the same equipment and operating under the same labor conditions, the difficulty of reaching a point for each mine that would be comparable for other mines is not so great.

5.—*Operation begins when the output has reached a certain percentage of the rated output of the mine.* This method is quite widely used and the percentage so far as I know varies from 50 to 66⅔ per cent. of the output. This gives a fairly definite starting point and one that is likely to be reached within a reasonable time, even though the full rated capacity may not be expected for an indefinite time in the future. It is also a point not influenced nearly so much as is the rated capacity point by market, labor and like trade conditions. The relation between this method and method No. 4—that is, the even break period or the time when the mine begins to make money—varies widely with local working conditions and depends, of course, upon the amount of invested capital, trade and labor conditions, etc.

To show the wide divergence in practice in this matter, at a number of mines that I have examined, operation accounts have been started when the mines have reached 30, 33⅓, 50, 55 and 60 per cent. respectively of their rated capacities or of the capacity subsequently obtained under full operating conditions, because rated capacity is also a somewhat indefinite point and many mines are worked to an overload and even though rated for 5000 tons, they may produce 6000 tons or more.



6.—*Operation begins when a certain arbitrary output per day has been reached or when the mine is prepared to produce such an arbitrary output.* In a number of cases with which I am familiar 1000 tons output has been assumed, and when this point has been reached the accounts have been changed from capital to operation, no attention being paid to the rated production capacity or whether the mine was making money or not.

This method may be fairly satisfactory where mines of approximately the same size are compared, but is not a satisfactory comparative method for mines of widely differing daily or yearly capacities.

Undoubtedly there are a number of other methods used by mining companies for separating capital from operating accounts, and I would be glad indeed to know of such and to see the reasons for their adoption stated as well as the advantages claimed for them set forth in the columns of *Coal Age*. I would also be glad to have a discussion of the methods outlined above, for although some of them may seem to be rather academic, all are at the present time being used and apparently giving satisfaction to the companies employing them.

A Crank Screwdriver

The driving home of large machine or wood screws is quite a tedious job if an ordinary screwdriver is employed. The improved screwdriver shown in the accompanying illustration will overcome any unnecessary

NOVEL FORM OF SCREWDRIVER

expenditure of energy and avoid injury to the hands, which often resuits if an ordinary screwdriver has to be used for any considerable length of time.

In operating the device illustrated, pressure is applied as usual, while the rotation of the screw, regardless of resistance, is made easy through the aid of the crank, which affords a much better leverage than the up-and-down form of screwdriver in everyday use.

Routine Determination of Specific Gravity of Coal

By ABRAHAM G. BLAKELEY
Pottsville, Penn.

SYNOPSIS — *The specific gravity of coal may be employed as a standard, more or less accurate, by which its fuel value and ash content may be judged. Difficulty may be experienced in manipulating coal crushed finer than "4-mesh," as the smaller particles tend to float in water. In such a case kerosene may be advantageously employed as the immersion medium.*

THE determination of the specific gravity of coal is of value for several reasons. The results are often utilized in calculating the quantity of coal in a given area underground. They possess utility in figuring the weights of different coals in cars or wagons, while in some cases they may help to decide whether coal came from some particular bed or from some certain mine or region. Specific gravity is a factor to be considered in the separation of coal from slate or bone or from cinder. This latter separation is of serious importance to operations recovering coal from streams.

Moreover, specific gravity results, if rightly interpreted, may be used as a rapid means of roughly judging the quality of coal from any particular mine. The specific gravity bears quite a definite relation to the ash content of coal. From any specified mine, coal samples of approximately the same ash content will have approximately the same specific gravity. Slate is heavier, or higher in specific gravity, than coal. Bone is intermediate between coal and slate in its ash content and in its specific gravity.

Ash Content and Specific Gravity

For anthracite coal, an increase of 1 per cent. in ash content will correspond to an increase in specific gravity of approximately 0.01. If a coal from a certain mine shows a specific gravity of 1.61, corresponding to 13 per cent. ash content, and a second sample from the same mine shows a specific gravity of 1.80, it may safely be assumed that the second sample will have an ash content approximately 32 per cent. Averages of hundreds of results on many different coals form the foundation on which this statement is based. Specific gravity can therefore be used as a quick means of judging the quality of a coal. Specific gravity results are not of equal utility to the consumer unless he knows from what mine or region the coal came.

Recently a sample of boiler fuel from a colliery boiler plant came in for test. There had been some complaint as to quality of the coal. The sample, after receipt at the chemical laboratory, was ground to about 10 mesh size, and a determination of specific gravity made. This was found to be 1.85 to 1.87, with an average of 1.86. Other samples of coal from this colliery had shown average results as follows:

Size of Coal	No. of Samples	Specific Gravity	Ash (Dry Basis)
Chestnut...	29	1.61	12.89
Pea.....	30	1.65	15.75
Buckwheat	30	1.67	18.20
Rice.....	29	1.75	26.24
Total and Average	118	1.67	18.27

From these results the ash corresponding to a specific gravity of 1.86 was calculated as 37.27 per cent., or approximately 37 per cent. ash.

In the meantime the boiler fuel sample was being finely ground (60 mesh or finer) for complete analysis. The ash was determined and figured to a dry coal basis. The result was 35.86 per cent., or approximately 37 per cent. ash.

Thus the specific gravity determination afforded a rough means of estimating the quality of this boiler fuel. The agreement as shown in this case, less than 1 per cent., will not always be so close. Nevertheless the specific gravity determination is certainly not without some value.

In 1909, together with my assistant at that time, Edwin M. Chance, I published a paper entitled "A Rapid Method for Determination of Specific Gravity of Coal." This method, as published in *Journal of Industrial and Engineering Chemistry*, December, 1909, is given below:

During the routine work of this laboratory it is necessary to determine specific gravity on a large number of samples of anthracite coal. As the methods available gave but little satisfaction commensurate with the time and labor entailed, we had recourse, after considerable experimentation, to the herein described procedure.

The apparatus, first of all, is simple, and may be found in almost any laboratory. The first requirement is a stout flask of about 250 cc. capacity, with a long and rather slender neck, terminating in a flaring mouth, such as the "copper determination" flask supplied by the Denver Fire Clay Co. This flask is to be marked at the base of the neck, either by a file scratch or by etching, and its volume up to this mark determined by means of a 100 cc. automatic pipette and a 100 cc. burette, graduated in 0.2 cc.

The burette should have a three-way stopcock and be connected with a reservoir either below or above the level of its top. In the former case suction is used to fill the burette, while in the latter case gravity is the means. It is better to use the elevated reservoir and gravity feed for the pipette. Of course, it is understood that a plain burette and pipette can be used, the form described merely having the advantage of rapidity.

The flask is calibrated as follows: The flask is rinsed with water, inverted, and allowed to drain for one minute; 100 cc. water is then added from the pipette, the flask is then filled to the mark from the burette. In calibrating by this method, inaccuracies in either pipette or burette do not militate against the accuracy of the specific gravity result, as the same method is pursued in the final determination.

The actual determination is carried out as follows; 100 grams of coal, previously crushed to about 4 mesh, and carefully sampled, are weighed to 0.1 gram, and placed in the flask. 100 cc. of water is run in, a 1-hole stopper fitted with bent glass tube and rubber connection is inserted in the mouth of the flask; suction is applied, and the flask is shaken, care being taken that no water is splashed into the glass tube. When air bubbles cease to be disengaged, the suction is interrupted and the stopper withdrawn. Water

is now run in from the burette till the flask is filled to the mark, care being taken to work down any coal which may have stuck in the neck.

The results may be calculated as follows:

$$\text{Specific Gravity} = \frac{100}{V_0 - V_1}$$

wherein V_0 = volume of the flask; V_1 = number of cc. water added to coal.

No calculation at all need be made if a table of reciprocals be available, as specific gravity = 100 × reciprocal of $V_0 - V_1$. As an example 100 grams coal were taken; volume of flask, $V_0 = 262$ cc.; volume of water added to coal, $V_1 = 197$ cc.

$$\text{Specific Gravity} = \frac{100}{262 - 197} = 100 \times \frac{1}{65} = 1.54$$

After making a determination the flask is emptied and rinsed, then allowed to drain for one minute, when another determination may be made.

This method is very rapid and so simple that an inexperienced operator can without difficulty make over 80 determinations per day accurate to within 0.02 unit of specific gravity. It is, of course, self-evident that this method has a wide range of applicability; the gravities of such materials as rocks, drillings, etc., may be determined with ease.

While the authors claim nothing new or radical in this process, still they submit it as a procedure by which results of moderate accuracy can be obtained with great rapidity, while the outlay for special apparatus is practically nil.

This method has been used since the date of publication and has given fairly satisfactory results. However, I have often had occasion to determine the specific gravity on samples of coal much finer than "4-mesh" size, and have in the case of coal samples of 10-mesh size or finer experienced some difficulty in obtaining reliable results. The fine coal has a great tendency to float on the surface of the water, thus obscuring the water level and making it almost impossible to judge the proper meniscus.

By a simple and inexpensive modification of the foregoing method thoroughly reliable results may be obtained on finely crushed coal. In place of water for the calibration and for the determination, ordinary kerosene or 150 deg. oil is used. The fine coal sinks readily in the oil and does not tend to obscure the meniscus. The oil after use is poured into a stock bottle or waste oil bottle and can be purified later when sufficient oil has been accumulated. Filtration through dry filter paper will remove both coal dirt and water.

After the oil is poured from the specific gravity flask, the flask is rinsed out by means of water, inverted, and drained as described previously. The little water left in the flask has no appreciable effect upon the accuracy of the results. The extra time taken in pouring the dirty oil into the stock bottle is more than offset by the time and trouble saved in reading of the meniscus and in general accuracy of results. Determinations can be duplicated readily to 0.02 unit of specific gravity.

In conclusion, I claim nothing particularly new in this method, but submit the procedure as a help to others working in similar fields of endeavor.

Coal is by far the most important of all the mineral products of the United States. Next to coal in importance is iron. Little Belgium, because of its important coal and iron deposits, has been a hive of industry, occupying a position as a manufacturing nation far beyond what one would expect from its limited area and population.—*Van Hise.*

Use and Abuse of Electric Headlights on Mining Locomotives

(*Continued from page* 1060)

to bring out clearly that no matter how good the reflector or how high the candle power of the light source, a good headlight cannot be obtained unless the light source is properly located.

In breaking a 4-amp. arc circuit a good switch must be used, one that will stand up for a long time. Fig. 24 shows a multiple break switch which meets fully the severe service incident to frequent interruptions in an arc circuit.

In Fig. 25 the switch is shown with the barrier removed and the cross bar broken away to show the connection between the adjacent switch blades *B*. This switch is of the quick-break type and has the advantage that it must be fully closed else the spring *C* will throw the handle back to the off position. When the switch is closed the bottom of the handle *D* fits in a recess in the cover at *E*, and is held there. The switch is exactly what the name implies—that is, multiple break. In ordinary knife switches the arc is broken in one place only. This multiple break switch breaks the circuit in four places.

The switch blades *B* are so shaped that at the instant of closing contact is made along the entire face of the clips *E*. Furthermore, the edge of the switch blade is bevelled so that a positive contact is insured. With this switch there is no such thing as point contact between the edge of the blade and face of the clip, but positive contact over an area greater than sufficient to carry the current. Such construction means long life to the switch parts.

This multiple break switch is a composite affair, which can be made into any one of five types by merely changing the back connections. It may be used for any of the following: Single pole, single throw (Fig. 26); single pole, double throw (Fig. 27); double pole, double throw reversing (Fig. 28); double pole, single throw (Fig. 29); double pole, double throw (Fig. 30).

These figures show the bottom of the switch with insulating cover plate removed. The various connections, as indicated above, are also shown. Connections 29 and 30 are seldom used in headlight work. However, this switch is useful wherever an ironclad, barriered switch is wanted. In every case the live line is connected to the front of the switch at *AA'*, and the headlight is connected *BB'*, *C* or *C'*, as is necessary for the connection desired.

The present balance of transportation is a great reduction in the proportion of the cars (normally) furnished for the transportation of coal. The railroads, however, are consuming their full quota of coal, so that while under favorable and natural conditions 35 tons of coal would be moved, out of each 100 tons of freight there is now being moved much less coal. The entire coal shortage is thrown upon the industries of the country and the domestic users, who, instead of having a coal supply equal to two-thirds of the total coal movement, are reduced to a small and continually diminishing ratio, and this in a time when every effort is being made to stimulate the industrial effectiveness of the nation.

Annual Meeting of the Coal Mining Institute of America

By FRANK H. KNEELAND
Associate Editor *Coal Age*

THE annual meeting of the Coal Mining Institute of America, held in the Chamber of Commerce Building and at the Fort Pitt Hotel in Pittsburgh, Penn., on Wednesday and Thursday, Dec. 4 and 5, 1918, was one of the most interesting and enjoyable that this organization has ever held. The biggest session, from the standpoint of numbers at least, was the institute dinner held in the English Room of the Fort Pitt Hotel, there being between 350 and 400 members and friends present.

The session of Wednesday morning was largely taken up with the election of officers. When the balloting was completed, it showed that the following men had been elected to the offices named: President, E. N. Zern; first, second and third vice presidents in order named, Messrs. Fohl, Maize and Arkwright; secretary-treasurer, H. D. Mason, Jr.; the executive board for the ensuing year will consist of Messrs. Affelder, Walsh, Pollock and Hanford.

After the election, the institute proceeded to the discussion of the first question in the question box. This read as follows: "What effect will the conclusion of peace negotiations have upon the labor supply in and about the coal mines?"

Without going into detail, the discussion on this question brought out the following salient features: It is believed that there will be no inrush of labor following the ratification of peace. Probably as high as 35 per cent. of mine laborers will return home. If the Central Powers have to pay large indemnities, laborers will probably attempt to leave those countries. The restriction of emigration and the indemnities will doubtless prove potent factors in the situation.

Some Actual Figures

A recent canvass of steel workers at a certain plant in Ohio showed that 25 per cent. of the laborers intended to stay in America. Another 25 per cent. anticipated returning to Europe for a short time, after which they would come back to this country. The balance, or 50 per cent., of the men canvassed intended to go to Europe and there remain permanently. In another instance, 56 men were interviewed at a coal plant. Of these, 25 expected to return to Europe. At another plant 40 men were canvassed. Ten of them, or 25 per cent, expected to return home. In another instance, of 55 miners canvassed 23, or 36 per cent., intended to return to Europe. Of 58 day hands, 28, or 48 per cent. of the total number, expected to return to Europe.

Thus, taking an average of all the foregoing figures, approximately 40 per cent. of the foreign-born laborers, or unskilled workmen, anticipate returning to the lands of their nativity. Under existing circumstances and the conditions that have prevailed throughout the world during the past five years, these men are not altogether to be blamed for their anxiety concerning the condition and state of their friends and relatives. On the other hand, with the reëstablishment of mail communications with what might properly be termed the beleaguered nations, or Central Powers of Europe, the anxiety of these men might be somewhat set at rest; and they may change their minds about returning to their native countries.

Another speaker on this subject stated that of 607 employees of one company, 87 anticipated returning to Europe temporarily, while 61 expected to go and stay. Thirty-six were doubtful as to what they would do, and 12 said they had friends who expected to come here.

It was suggested that some of this exodus of labor might be counteracted by inquiries concerning friends and relatives in Europe directed through the American Red Cross. Such inquiries might well be handled through the offices of the various coal companies.

Dare They Do It?

Still another speaker pointed out that the countries of Southern Europe are now laboring under popular and somewhat unstable government. It is doubtful if these countries could force their peoples to remain if they wish to emigrate. It was pointed out that under present conditions the various European countries will be much more careful of the restraint imposed upon their citizens than was the case before the war. Wages here are high compared with Europe, and general mining and industrial conditions are much better. These will doubtless play an important part in the labor question after the final peace ratification.

Question 2 reads as follows: "Should the drawing of mine timbers be penalized under the safety standards in computing compensation insurance rates; if so, under what conditions?" The discussion of this question was comparatively short, the principal point brought out being that mechanical means, such as chains or post pullers, should always be used in removing timbers and that this work should be done under the supervision of a competent and careful foreman or subforeman.

Question 3 was then taken up. This question reads: "To what extent can the water-gage chart be used as an index to the ventilation conditions in a mine?" The consensus of opinion brought out in this discussion seemed to indicate that while the water gage was a good general indication of ventilation conditions, in many instances at least the fluctuations of the recording pen, probably due to eddy currents in the mine passage, were so violent and frequent as to render the record of little specific application. It was pointed out, however, that these rapid and violent fluctuations might be somewhat steadied down by almost closing the connection between the recording gage and the orifice of the tube extending into the air passage. Thus, if a valve was located in this air pipe, cracking the valve instead of

opening it wide would tend to steady down the recording pen of the instrument.

The fourth question, "Has the law permitting the employment of non-certified officials in coal mines been detrimental to their (the mines) efficient and safe operation?" brought out considerable discussion, which at times waxed hot and almost acrid. It was stated that the change in the law permitting the employment of non-certified foremen had had no effect in the anthracite field. Some of the bituminous operators have taken advantage of this law and employed men who did not hold certificates. It was admitted that uncertified men were often incompetent, and that a certificate was an index but not a guarantee of competency.

One speaker stated that 28 men in one inspection district are mine foremen without certificates, and that accidents have increased in this district largely on this account. It was also brought out that due to the high wages paid to the miners and comparatively low wages paid to mine foremen, many certified men were loading coal.

One speaker brought out the point that operators are not always competent to pass upon the proper qualifications for their mine foremen, and there is legally no one to pass upon the operators' competency in this direction. One state mine inspector was emphatic in his assertions and made the statement that the operator who allows an uncertificated man in an authoritative position in his mine is a criminal.

Discussion of Question 5, "What are you doing to increase the efficiency and steady working of your employees: with what success are you meeting?" was then taken up. It seemed to be the consensus of opinion that in order to secure continuity of service from miners it was necessary to offer them certain inducements other than high wages or bonuses. In other words, an incentive to work must be given. Among the inducements that might be offered, the sale of company houses was mentioned. In some instances, such a plan worked well. One company tried it some years ago and sold about 30 houses, but this idea does not work with equal effect during good and bad times. The men regard the purchase of a house as a kind of fire insurance—that is, an insurance against getting "fired."

Full Payment Means a Long Wait

Another speaker brought out the point that it would probably be better to sell the man his plot of ground first and then build or offer to build upon it a suitable house according to the man's own plan. Many of our miners do not like the idea of paying out money, so much a month every month, for a considerable length of time and having nothing definite—that is, nothing in the form of a deed—to show for their investment until the entire amount is paid up. This plan of selling the land first and the house afterward has been tried in the anthracite regions with good success.

As another inducement for his men to stay on the job, one operator gives his store patrons a check covering the profits of the store. This is not a due-bill on the store, but a real check redeemable in real money at any bank. This has had a good effect upon the men. Probably, however, none of these expedients alone will answer the purpose, and it will doubtless be necessary, if men are to be retained in satisfied employment, to offer many other inducements than those mentioned. Among these might be noted proper living conditions, good school facilities, sanitary surroundings, etc.

Question 6 read: "Are roller-bearing wheels too delicate for mine cars?" This question brought forth some discussion. It was stated by one speaker that it was a wrong principle to put roller bearings of any kind in any car wheel proper, the best place for them being in a journal box. Another speaker, who illustrated his talk with several lantern slides, showed roller bearings that had been in use for several years without losing their efficiency. It would appear that the test of continuous use would be the best and only satisfactory answer to this question.

Alternating vs. Direct Current

Question 7 was next taken up. This question read, "Is the underground use of alternating current more hazardous than the use of direct current?" One speaker stated that in one operation several alternating-current mining machines have been successfully used for something like six years. These have given no more difficulty nor have they proved any more dangerous than the ordinary direct-current machines. Another stated that alternating current of equal voltage appeared to be safer than direct current. This is probably due to the fact that with direct current, touching one conductor is enough to give a person a shock, while with alternating current it is necessary to touch at least two.

Another speaker discussing this question stated that he had always considered 440-volt alternating current as being as dangerous as 500 volts direct current, but that he considered both of these voltages too high. In his judgment, it was unnecessary to carry the potential of underground circuits, at least those so placed that men might come in contact with them, at above 220 volts for alternating current or 250 volts for direct current. In stationary operations under ground, it is in many instances possible to carry high-tension wires properly insulated in conduits directly to the terminals of the machine. The alternating-current motor, since it is usually boxed in and has no live parts touchable by anyone if properly and permanently installed, is comparatively safe. However, high voltages underground should be avoided if possible.

The discussion narrated above carried the meeting to the close of the afternoon session. The next session was in the evening, in the English Room of the Fort Pitt Hotel, and consisted primarily of supper. After the eatables had been disposed of and cigars had been lighted, a short report of the condition of the institute was made by the retiring president, Mr. Affelder. This showed the institute in a flourishing condition, both in numbers of members and in finances.

President-elect Zern was then introduced and made a few remarks. Unfortunately, James B. Neale, production manager of the United States Fuel Administration, could not be present at the institute supper, as his presence was necessary in Washington.

Dr. Downey was then introduced and made a short talk on industrial insurance and workmen's compensation. The cost of this insurance in the bituminous region averaged about 5c. per ton, while for anthracite

it was from 8 to 10c. During the past few months, for each million tons of bituminous coal mined there have occurred three deaths, one disability and 20 to 30 compensable disabilities, or those entailing the loss of two weeks or more time. He stated that coal mining was inherently hazardous. In cigar manufacturing the hazard was represented by $0.0015, while for coal mining it was represented by $2.

Captain H. D. Trounce, of the 606th Engineers, was next introduced. Captain Trounce, at the beginning of the war, enlisted in the British Royal Engineers, and took part in the underground mining in Flanders and in the Vimy Ridge country. He vividly portrayed the excitement and danger of mining under No Man's Land.

Seward E. Button, successor to James E. Roderick, deceased, was then introduced. He read a short paper complimenting the individual members of the organization on their work during the war and pointing out the possibilities of the future. He stated that the casualties in mining during the times when every effort was being made to increase and maintain a high output were only slightly greater than those in peace times. In conclusion, Mr. Button urged the Americanizing of the foreigner. He stated that naturalization was not sufficient to make a good citizen out of the man who, for various reasons, seeks our shores and sojourns among us.

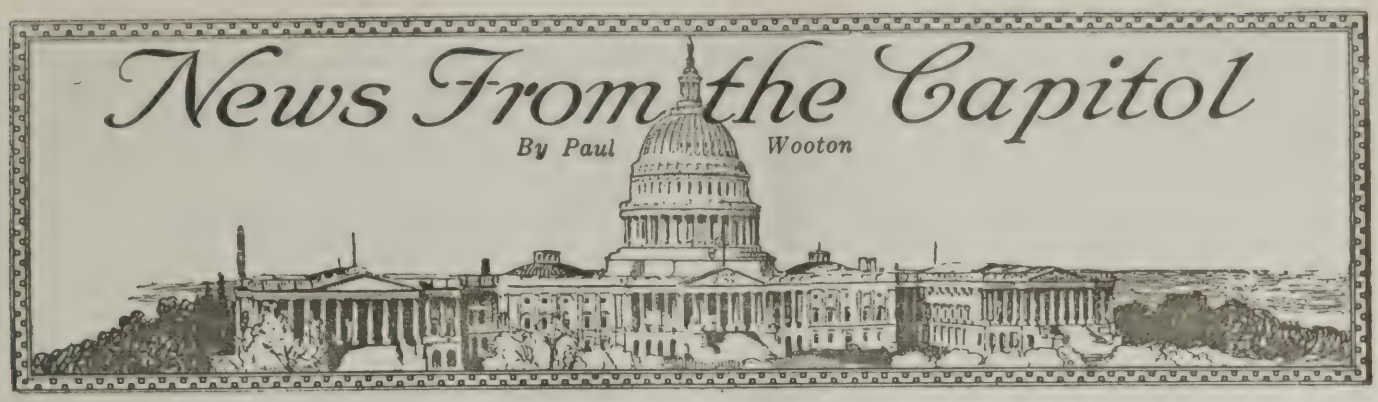
Describes Gas Investigations Work

Colonel G. A. Burrell, chief of the Research Division of the Chemical Warfare Service of the United States Army, was then introduced. Colonel Burrell has had charge of important gas investigations work for the Government, and was well qualified to speak upon his subject. He explained that before the war started, Mr. Manning, of the Bureau of Mines, had offered the War Department the facilities of the bureau so far as gas study was concerned. His offer was accepted and the present research organization is largely the outgrowth of this acceptance.

Gases used in warfare at present are of four types: Tear gas, respiratory gas, skin irritants and sneezing gases. The respiratory, or lung-attacking, gases were first used, the first ones to be employed consisting of chlorine and phosgene. These, while quite deadly in their effect if inhaled in sufficient quantities, could be easily guarded against with suitable gas masks. The most difficult gases to contend with have been the skin irritants, of which mustard gas has been the one most commonly used. Colonel Burrell explained that simultaneously with the perfection of gases had come the perfection of gas helmets. These have been developed from simple gauze bandages worn over the mouth and nose and saturated with certain chemicals to the present so-called "fighting helmet" employed by the United States troops. This helmet is so arranged that breathing in or through it is little more difficult than breathing without any mouth and nose covering. Also, the instrument is so arranged that the inhaled air, before reaching the mouth or nose, impinges upon the eyeglasses or windows in the device. This simple expedient insures clear visibility at all times.

On Thursday morning, Dec. 5, the institute reconvened in the auditorium of the Chamber of Commerce Building. Consideration of Question 8 was then taken up. This reads: "In what way can the conservation of material and supplies be best effected both inside and outside the mines?" The principal paper in this discussion was delivered by Mr. Jones, of the Du Pont company, and related to the storage and use of explosives. As this paper will appear in the Dec. 19 issue of *Coal Age*, a further discussion of it here is unnecessary.

Question 8 was the last in the question box, and after the discussion had been disposed of the institute proceeded with the presentation of four extremely interesting papers. The first of these was "The Elimination of Power Losses," by Graham Bright, engineer in charge of the Mining Division of the Westinghouse Electric and Manufacturing Co., of Pittsburgh. This paper was printed in *Coal Age*, Dec. 5, page 1021, and therefore requires no further discussion here, as it can stand on its own merits.



A paper entitled "Underground Coal-Loading Machinery," by E. N. Zern, was next presented. This was elaborate and full and took a considerable time to prepare. Mr Zern was at many times thoroughly flooded with questions pertinent to the use of mining machinery.

"The Use and Abuse of Headlights on Mine Locomotives," by W. K. Mackall, was presented at the afternoon session. This was profusely illustrated with lantern slides. This paper appears in the current issue, and, like the one mentioned above, can stand on its own merits. "The Preservative Treatment of Mine Timbers as a Conservation Measure" was the next paper, and was presented by Kurt C. Barth. This paper was also printed in *Coal Age* for Dec. 5, beginning on page 1025.

This completed the program for the afternoon meeting. Much interest and enthusiasm were manifested, and no one who attended the meeting could come away doubting the usefulness and efficiency of the organization. Much of the success and present strong position, both numerically and financially, of the Coal Mining Institute of America has been due to the zeal and untiring efforts of the retiring president, W. L. Affelder. The incoming president, or the one for the year 1919, is also a man of much zeal and thoroughness. If he handles the affairs of the institute as thoroughly as he handled his subject on underground coal-loading machinery, no one need worry concerning the future of the organization.

Will Maintain Prices to End of Coal Year

Announcement that the price schedule might be lifted and the zoning system discontinued on Dec. 15 brought forth such a protest that it is understood no change will be made prior to Apr. 1, the end of the coal year. It would be manifestly unfair to dealers, it is held, who have been forced to stock up with low-grade coal. If the bars are thrown down at this time, it would be next to impossible to dispose of their holdings with higher grade coals on the market. In the same way, it would be unfair to industrial consumers who had stored lower grade coal. In addition, it is believed the effect on labor would be such as to precipitate a serious situation.

Fuel Administrator Garfield Resigns

Dr. Garfield's resignation came as a surprise to the Fuel Administration, as well as to the general public. The interpretation placed upon his resignation was a surprise to Dr. Garfield himself. The facts of the matter are these: In an informal personal letter Dr. Garfield called the attention of the President to an urgent situation which had been precipitated at his college by the withdrawal of the student army training corps. He explained that the situation is such that he feels it his duty to devote a portion of his time, from now on, to the college. As the President was on the point of leaving for France, Dr. Garfield felt that it would be only proper that he place his resignation in the President's hand with the understanding that he would continue to give the Fuel Administration a portion of his time. It is understood that the President accepted the proposition exactly as stated by Dr. Garfield. The announcement, unsupported by the other facts surrounding the tender of the resignation, led to much speculation, some of it going so far as to declare that a break had occurred between the President and Dr. Garfield because Dr. Garfield did not approve of the President's trip to France. It is Dr. Garfield's intention to spend one day each week, or more if necessary, looking after Fuel Administration matters, even after he takes up anew his duties at Williams College.

Will Investigate Availability of Lignite

The bill providing for an investigation of lignite coal has been reported favorably to the House by the Committee on Mines and Mining. The committee amended the bill to exclude peat and reduced the appropriation from $150,000 to $100,000. The bill was introduced with the explanation that "the object of the investigations proposed by this bill is to demonstrate the commercial practicability of the use of our vast lignite deposits, which constitute one-third of the coal deposits of the nation, a vast volume of these deposits being upon Government land, and owned by the Government. The carbonizing of lignite has passed the laboratory stage, and the problem now to be solved is to work out the results obtained in the laboratory on a large commercial scale, so as to demonstrate its practicability from a commercial standpoint to such an extent that private enterprise and capital will undertake the development of this wonderful resource." The committee submitted a report which goes into an extensive analysis of the present lignite situation.

Relinquishes Control of Soft Coal

Requisitions made by the Fuel Administration for shipment of bituminous coal to industrial plants have been canceled. In the future all industrial users must arrange for their own supplies. Retail dealers, hospitals, schools, public utilities, the Government departments and state and municipal agencies also have been asked to look out for their own fuel. The Fuel Administration, however, will maintain a portion of its distribution bureau so as to look out for such consumers and domestic users in case of necessity.

Recent Changes in Coal Zones

The market for the high-volatile coal in the Logan and Kanawha fields has been increased by the modification of Zone M-2. The high-volatile producers in Kentucky also may sell over a larger territory by the change in Zone M-4. Zone L also has been changed so as to afford additional territory to the coal produced in the Kanawha district. The consuming district of Zone M-3 also has been enlarged to permit of wider shipments of the high-volatile coals of West Virginia and Kentucky. Similar action has been taken in Zone M-1.

Many Fuel Officials Resign

W. H. Warren, of Richmond, Va., who has been in charge of coal consumers' needs in several of the southern states for the Fuel Administration, has resigned. J. O. Knight, of Baltimore, who had charge of similar work in Pennsylvania, Maryland and Delaware, also has resigned. Alexander Yule, of St. Louis, who directed the distribution of blacksmith coal, also has returned to his personal business. The resignations were handed in because the changing conditions have so reduced the work as to make the services of these men unnecessary.

To prevent any increase in the price of gashouse coke, based on the recent anthracite advance, an order has been issued fixing the price on the basis of anthracite prices as of Oct. 1.

Coke distribution has been placed in the hands of state fuel administrators. They also may give permission to use coke as a domestic fuel in cases where they deem it necessary.

Canadian permits for imports of bituminous coal into Canada will not be required in the future, the Fuel Administration has announced. The requirements with regard to anthracite shipments remain the same.

The Red Cross seeks a 100 per cent. membership for 1919. Children and parents with one accord should enlist under the great international banner of brotherhood and service, for, by its ministry of mercy, the Red Cross will complete the victories nobly won in the foughten field. None are too young to be helping toward a better and brighter world.

Contest Between the Head and the Hand

IN THE United States, there have always been some men who, laboring with their hands, have made large earnings. Those who labor with their heads, especially those in inferior capacities, have too often been quite a little jealous of the larger incomes made by these manual laborers. "Brain labor," they assert, "should receive greater consideration." The complaint is general that "I have been 25 years acquiring my experience, and yet I only make as much as a man who works with his hands."

The grumbler overlooks the fact that the manual laborer has been getting during that time, perhaps not what we somewhat loosely term "experience," but at least adaptability to his tasks—dexterity, strength, hardiness, hardness and what not. Perhaps his growth toward greater physical development of the kind needed for his work soon reached a limit, but at least the same might be said of the brain worker. If the latter has progressed from one form of employment to another, he doubtless lost in that progress many of the peculiar adaptabilities he successively obtained. If he stayed at the same work, it is likely that his advance largely ceased after the first year of his employment. It is not clear therefore that years of experience at mental labor have any more claim than years of development at physical labor.

There are, of course, certain employments for which much mental equipment is needed and an observation extending over years—employments requiring special aptitude; yet occupying positions of that kind are often men who do not have that aptitude but claim the emoluments which commonly go with the position or are believed so to go, or which we believe should go with such a position.

To these men it seems they should be paid rather by the measure of their ambition and pretentions than for the measure of their mental attainments. A passable mechanic may have been spoiled to make an indifferent brain worker, and the product, a substitute of inferior value, proclaims its right to payment as of the material for which it is substituted.

As a matter of fact, the plodding workman who denies himself the ambitions that we all more or less have—the ambitions to exercise authority, to wear fine linen, to labor with the head instead of with the hand—is entitled to a reward for his patient plodding at unwelcome toil. His task may be one of endless uninteresting repetitions; it may be hedged around with a multitude of discomforts and dangers; it may bring little reward but money; it may promise only irregular employment; it may have to be conducted in solitude; it may involve a weary travel to work night and day; it may necessitate changes of clothing and time-consuming ablutions; it may keep a man from his family.

It is not unreasonable, therefore, to conclude that certain kinds of mere manual labor may well pay higher wages than certain kinds of brain labor, especially seeing that there are many in all walks of life who are now fitted by education for the latter.

It is often alleged that the worry of authority should be compensated as well as the labor of its exercise. But no one is paid to worry. As worry is a disease, it should rather be penalized than rewarded. Some men fag early at their work. We cannot pay them for their abnormal fatigue, and we cannot reward a man for abnormal worry.

The man who worries easily may be, it is true, a good brain worker, just as a man who is fatigued easily may be a good mechanic; but the worry, like the fatigue, cannot be made the basis of compensation. A healthy spirit would be as free of one as the other, under normal conditions, so the less said of worry the better.

Again, the economic value of the brain worker is alleged as a cause for consideration, and this may be or may not be a good argument. Twenty-five men under the direction of a foreman may do as much as fifty men without. "Clearly," says your economist, "that one man earns as much as twenty-five and is entitled to compensation accordingly." That is true if the character of the boss is the cause of the increased work; but if any one of the twenty-five other employees could qualify in a short while to do as well in the position of boss as the twenty-sixth, what becomes of the title of the foreman to the larger salary?

With so many persons supplied by the state with the first steps toward a qualification for a job of headwork, the position of the brain worker becomes less and less remunerative. More and more are willing to give $5, $10, $20 a month to be boss, and are willing to accept the worry of the task for the pleasure of the exercise of authority. It is not a man of low instinct who seeks such authority. The man may be courteous and modest enough in its exercise, but he likes the intellectual development that authority confers, and he craves something on which his mind may continually busy itself.

There are two contrary theories of wage compensation. We hold to both of them as each in its turn suits our best interest. There is the rule of the "fair" wage and that of the "economic" wage. A brain worker may save others so much labor and unpleasant toil that his work has a high economic value. It is impossible to determine just what that wage is by argument. We are forced back into the theory of the economic fatalist, that the reward of the employee is proportioned automatically to the economic value of his services, or at least tends to be so adjusted.

It is about as true as the doctrine of providential fatalism. We are now being generally taught that "divinity" does not wholly "shape our ends, rough-hew them how we will," and that we can avoid sickness by

prudence and accidents by care. So does it fare with our belief in economic fatalism. Roughly speaking, economic laws do put us in certain categories and provide what the payment shall be for certain services, inconveniences and helpful abnormalities of character, mind and skill, but there is a degree of freedom also entering in. We break away from the economic fate by individual action, and still more by concerted action. Still the economic law will on the whole determine more readily than any law of fairness the right status of an employment.

Everywhere is the force of gravity, yet there are waves in the sea. Everywhere are economic laws, yet there are men over-rewarded and men under-rewarded, and all we can say is that a fair wage based on mental premises would not be as likely to solve the problem as correctly as it will be solved by the ebb and flow of the economic tide.

Let us not be jealous of manual labor. If it be not worthy of the higher rewards it has been getting, the law of economics will correct the unfairness by a readjustment of the wage paid for the work of the brain. The readjustment, if warranted, will inevitably come, though there may be some delay before it is accomplished.

Just Enough Is Never Enough

THE BRITISH are advocating Government ownership for railroads. They say that with a national monopoly it is possible to nicely regulate means to ends so that there will be less waste of labor and material. Before the war Great Britain often had three trains running where one or two now carry all the people who desire to travel. The project all sounds unanswerable till we remember how Great Britain has tried to solve just this same problem of adjustment in the telephone service. The British Government has always had that service under its exclusive charge. It has always tried to balance means and ends, but the ends always overtook the means. There was always more business than facilities for business, more demand than supply. Britannia, telephonically, has always had a hobble skirt.

Whenever industry is asked to make its demand, before that demand is supplied, by the very nature of things the supply will lag behind the demand, and even the demand itself will lag. We have been accustomed to have corporations coaxing us to develop our business methods. Now we are likely to have Government managers requesting us to do without certain accommodations which we are anxious to receive and willing to pay for. We shall be asked to wait till there are enough persons making the demand to make the improvement 100 per cent. effective. We shall find all our privileges restricted and we shall not be allowed to complain, for to complain of the Government is to make a protest against the flag.

One of the beauties of profitable private ownership is the bounty of the accommodation it supplies. When times are normal we do not have to make reservations in advance if we desire to travel. We do not have to requisition railroad cars months in advance. But under Government ownership and that wonderful system of balancing of needs to provisions, we shall always find that there is no surplus. That which has made us wage the war successfully has been our reserve of force and material. Had we been bound, as Government regulation would have us bound today, we could not have turned ourselves in the narrow quarters of our accommodations.

Whether the Government holds on to the railroads or relinquishes them, we face an increase in the transportation charges. We wish to go back to the old day of too much railroad rather than too little railroad. We want too many cars, too many miles of track, too many trains rather than too few. The railways broke down because they were given minima instead of maxima. They will break down again, and repeatedly, if they are going to be run or regulated by a pinchbeck policy. A little extra power will do no harm.

An operator said once that he had no trouble with his engineers. He said they figured and figured and figured, and then added 10 per cent. for contingencies. Then the operator took the figures and doubled them. The result gave perfect satisfaction. What was a good rule for that operator is a good rule for the nation.

Our theoreticians at Washington are like the man who rationed his horse a little less every day till his steed was subsisting on one straw every twenty-four hours. Just when this bold investigator in the art of horse *ménage* was about to make his triumph public, the horse died. It will be the same with the iron horse.

If we regulate prices for transportation to suit certain favorable conditions, if we place them so that only the well favored prosper, we shall have no railroads. The survival of the fittest is rubbish. There are so few fittest. At best it must be the survival of the fit. But the regulators of industry in their zeal would rule out all but the fittest and the fittest cannot do all the work of the world. Some of the burden must be carried on the backs of the merely fit.

Coal in the Readjustment Period

THE coming of peace has brought with it complications no less involved than those of war. After creating an abnormal demand for the products of industry, the Government has been forced to partially liquidate its war business. As a consequence, industry is now driving about in an endeavor to readjust itself to a peace basis. In the interim the coal industry finds itself marking time.

In an effort to inject a little action into this listless atmosphere, it has been suggested that the Fuel Administration remove all restrictions on the shipment and sale of soft coal. In other words, that the trade be once more placed upon a competitive basis. If the Administration complies with this suggestion the industry will be confronted with a highly interesting situation.

Will the relinquishment of control provide an additional market for those Middle West mines now restricted in their output? What will become of the many contracts that have been entered into with the approval of the Fuel Administration and stipulating the last Government price as the ruling quotation for the life of the contract? A number of other questions present themselves, and it is evident that it will take the best brains available to answer them to the satisfaction of all the parties concerned.

DISCUSSION BY READERS

Hindrances to Coal Production

Letter No. 8—The letter on this subject that appeared in *Coal Age*, Nov. 7, p. 873, interested me greatly. I was led to think, however, that it laid too much emphasis on the matter of intemperance among the miners. There is, of course, no question but that booze plays a large part in reducing the production of coal. Often, when you ask a man why he is idle, he will tell you that he is sick; but, in fifty per cent. of the cases, investigation will show that the sickness started in some saloon, or possibly a christening, or a wedding celebration.

A volume, almost, could be written on the many different things that interfere with the efficient operation of the mine and hinder the production of coal. They are multitudinous. Some of the more important causes are the following: Bad or worn-out machinery; insufficient equipment of the kind best suited to perform the work required; bad haulage roads; poor drainage; defective ventilation in the mine; and, last but by no means least, poor living conditions for the miner and his family. All of these and many other things help to keep down the productiveness of a coal mine.

Effect of Poor or Inadequate Equipment

Experience in different mines has led me to believe that, perhaps, the greatest loss in coal production is due to worn-out machinery and antiquated methods of mining. At one mine, for instance, the coal was hauled by a gasoline motor that had performed its share of service a year or two before it fell into my hands. We would work on that motor for hours to get a day's run out of it, only to have it break down when we were in the greatest need of coal. At such times, the entire mine would stand idle, until we could get the machine into running order again. The same is true of other mine equipment, such as pumps, mining machines, and like apparatus used in the operation of a mine.

Frequently, we find mines where the seam pitches so as to cause heavy grades in the rooms, and the miner is compelled to push his cars to the face. Sometimes, it is all that he can do to get his car up the grade and in a position to load. The energy he expends in this manner should have been used in mining and loading his coal. Although operators are now waking up to many of these conditions that hinder the work and reduce the output of their mines, it is a fact that too many of such hindrances still remain.

Living Conditions Assist or Retard the Work of Getting Out Coal

Many people do not realize how large a part bad living conditions play in the production of coal. When a miner has a good cozy house to go to, after his day's work is done in the mine, it gives him an incentive to work harder, in order that he may make his little home even more comfortable. He becomes more thrifty and an increase is noticeable in his daily tonnage.

While the things I have mentioned thus far are matters that the operator must improve if he would increase the capacity of his mine, there are other things we can all do that will greatly assist in getting out more coal. The efficiency of the foreman, for example, plays no small part in making a mine produce a good tonnage. In the majority of cases, the falling off of the day's output is largely due to the mistakes of the foreman or his lack of attention to matters in his charge. Poor work performed by trackmen, timbermen and other daymen, resulting in bad haulage roads, poor drainage, bad air at the working face because of leaky doors and stoppings, make it impossible for a mine to produce to its full capacity.

A matter of greatest importance is the disposition of a foreman to ignore the little troubles of his miners, which a single word or act of his would help to overcome. An inexperienced miner will often be observed performing his work in the hardest possible manner. The helping hand of his foreman, at such times, will result in the man's getting out more coal by far than if the foreman resorted to cursing and swearing or reprimanded the fellow sharply for his ignorance. In closing, I want to say that we can all do something to increase the production of coal if we only use our heads a little more than we have been in the habit of doing heretofore.

J. H. Tipton.

Landstreet, Penn.

Calculating a Room Switch

Letter No. 1—I was glad to see the question of a correspondent, in *Coal Age*, Oct. 17, p. 756, asking for the proper dimensions of a room switch and how to ascertain the number of frog that will give the best satisfaction. To my mind, this is one of the most important features to be considered in the development of a new mine, and one that is often not given the attention it requires. Unless that is done, much trouble is bound to follow.

While it is customary for a company to have this work done by a mining engineer, it is well for every mine foreman to be able to work out such problems for himself. It will enable him to understand better when a room switch is well laid. The method of calculating the number of frog to be employed and the required dimensions of a mine switch has been fully explained at different times in *Coal Age*, and I have found that if the figures given are followed there will be no trouble.

Having selected the right frog, find the length of lead rail required by multiplying the frog number by twice the track gage, in feet. Then, find the radius of the curve by multiplying the length of lead rail by the frog number. In a long experience in laying

switches in a mine in southern Illinois where gathering motors were used, I found no trouble when using these rules.

Practically, the first question to be decided is, What frog number will best suit the conditions. In the case mentioned in this inquiry, there should be no serious trouble in laying down a switch to enter a room, which is here said to be turned with a width not exceeding 12 ft. In laying the curve beyond the frog, however, it may be necessary to crowd the rib of the room neck and widen out on the opposite side.

Practical Conditions Determine Frog Number

In deciding these questions, one must know the kind of haulage that is to be used, the weight and size of locomotive, wheelbase and size of wheel and the speed at which the cars must move. These data will greatly assist in choosing the right frog. For example, in the present instance, let us assume that a gathering motor weighing 6 or 6½ tons is to be used, and the capacity of the mine cars is 2 or 3 tons. In that case, I would select a No. 2 frog. The track gage being 42 in. (3½ ft.), the length of lead rail required is, then,

$$l = 2gn = 2 \times 3\tfrac{1}{2} \times 2 = 14 \text{ ft.}$$

The radius of the curve, in this case, is

$$R = ln = 14 \times 2 = 28 \text{ ft.}$$

I would use a latch not longer than 3½ ft. In running gathering motors and laying track after them, I have found it a good scheme to have the latch short enough that it can be kicked or moved freely between the first car and the locomotive pushing the trip. In other words, the last wheel of the rear car of the trip must have cleared the latch before the motor trucks reach it. I have often found this to be a practical point worthy of observing carefully.

Cleaton, Ky. Ostel Bullock.

Letter No. 2—Replying to the request of a correspondent who asks for the proper dimensions of a room switch, and the number of frog that will give the best satisfaction under the conditions he mentions, I am glad to give him the benefit of my own experience along this line.

Owing to the bad-roof conditions it is stated that the rooms, in the case under consideration, cannot be turned a greater width than 12 ft., and I assume that the entry is of the same width. This being the case, it will not be possible to act upon the old-time slogan of the best practical mine tracklayers, which was, "The longer the switch the better the haul," and adopt a longer switch than the space will admit.

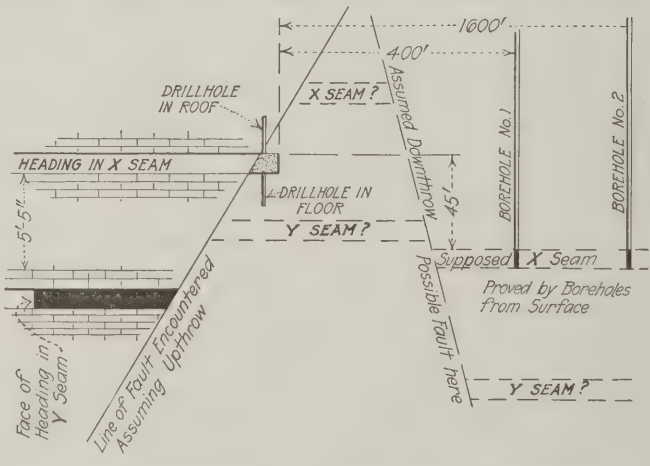
The correspondent has failed to state the system of haulage he is to employ. However, as this is a new mine, one might assume that the intention is to use a gathering motor for collecting the cars from the rooms. It is stated that the track gage is 42 in. and the length of car 8 ft. 9 in.

For a number of years, I have been hauling coal over all kinds of track and in the use of almost every kind of haulage system, including mule, rope and motor haulage, and want to say that the old-time slogan just mentioned is a most important item in mine haulage, if one is to secure the best results. My plan is always to use as light a curve as possible, which means the lengthening out of the switch rail.

In the present instance a 12-ft. collar bar will span the mouth of the room, and this must be set so as to favor the longest curve possible on the room switch. Taking everything into consideration, let me suggest that a No. 2 frog should be used. Estimating the length of switch rail for this frog, according to the method previously described in *Coal Age*, [Vol. 10, p. 673] we find for the required length of this rail,

$$l = 2\ g\ n = 2 \times 3\tfrac{1}{2} \times 2 = 14\ ft.$$

This is the length of the lead rail reaching from the point of switch to the point of frog, using a No. 2 frog, when the track gage is 42 in. or 3½ ft.



In order to bend the rails to the proper curvature, the length of the radius of the track center is calculated by multiplying the length of switch rail, as just found by the number of the frog, which gives, in this case, 2 × 14 = 28 ft. radius to the center line of the track. I shall be glad to learn of the experience of others along the same line. Claude W. Carruth.

Edwardsville, Ill.

Locating the Coal Beyond a Fault

Letter No. 2—After a careful study of the sketches showing the profile, cross-sections, plan of working and legend, submitted by "Superintendent," in his inquiry, Oct. 24, p. 797, it appears to me that he was proceeding on the right track in driving entries and prospecting the line of fault to ascertain its nature. However, it is my belief that the main headings were not driven far enough through the fault before putting the drillholes up and down in the roof and floor of the heading.

It is clear, from a study of the six cross-sections given in the inquiry, that this fault is an upthrow.

UPTHROW FAULT FOLLOWED BY A POSSIBLE DOWNTHROW

Such being the case, unless the main heading was driven sufficiently far through the fault before putting a drillhole up in the roof, the hole would only penetrate the faulted strata or dead ground, as I have shown in the accompanying figure. The hole put down in the floor of the heading was probably not drilled deep enough. Had this hole been carried a few feet deeper, it is my opinion that it would have found the Y seam, just below.

Referring, now, to the two boreholes sunk from the surface and which appeared to have penetrated the X seam, at a greater depth than was expected, so that

it was thought that the coal struck was the Y seam, it is possible that another fault exists between the one first found and the borehole 400 ft. in advance of the heading. This second fault would be a downthrow, as indicated by the dotted lines in the figure. I suggest this as a possibility, but the actual condition can only be determined by prospecting and carefully studying the strata penetrated by the boreholes. This possible position of a second fault, as shown in the figure, assumes that the first fault is an upthrow and that the coal struck by the boreholes was the X seam.

Further Prospecting Needed

Much satisfaction would have resulted by continuing No. 1 borehole, sinking it 50 ft. deeper. The information thus gained would have warranted the extra cost of drilling. In addition to sinking these holes deeper, I would push the main heading, in the Y seam, to the fault; and, at the same time, drive an uprise from the face of the right-hand main heading, in the X seam. This uprise, or slope, should follow the slip, keeping well in touch with the footwall so as not to miss finding the coal should the fault prove to be an upthrow, as I have assumed. I would also bore downward in the floor of the main heading at least 60 ft.

Should these efforts not succeed in locating the X seam beyond the fault, it will be necessary to drive an uprise on the slope, starting from the face of the heading, in the Y seam, where it reaches the fault. In closing, let me say that the two boreholes mentioned in the inquiry as driven from the surface, appear to be sunk in a valley or hollow. It is well to remember that hollows or valleys on the surface often mark a line of fault or trouble in the strata, and holes in such places may not give the best satisfaction.

Linton, Ind. W. H. Luxton.

Letter No. 3—Reading the interesting discussion that has appeared in *Coal Age*, regarding the method of locating the coal beyond a fault, reminds me of a slip that we encountered in our mine some time since, and which is very similar to the conditions described in the inquiry that started the discussion, Oct. 24, p. 797.

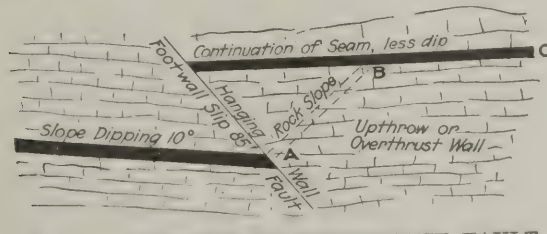


FIG. 1. SHOWING AN OVERTHRUST FAULT

In our case, however, the fault was an upthrow, while the one described in the inquiry is seemingly a downthrow.

Our mine was opened by a slope pitching 10 deg. The condition met when this slope struck the fault is illustrated in Fig. 1. Prospecting showed that the continuation of the coal seam was above. The fault was found to be one that is best described as an overthrust, the strata having been forced upward when the break occurred. The dislocation was 85 ft. measured on the fault line.

In order to continue the work of mining in the seam beyond this fault, we drove a rock slope from *A* to *B*, as shown in the figure. The seam beyond the fault had considerably less dip. An inside hoist was installed at *B*, to haul the coal from *C* to *B* and lower it from *B* to *A* through the rock slope. From the latter point it was hauled out of the mine.

Allow me to suggest, here, that from the description given in the inquiry, it appears to me that the fault

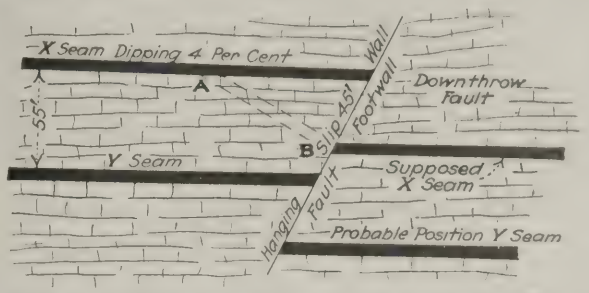

FIG. 2. ASSUMING FAULT TO BE A DOWNTHROW

mentioned is a downthrow, as shown in Fig. 2. There is little doubt, in my mind, but that the coal found in the boreholes sunk from the surface belong to the X seam. In that case, the best plan to follow would be to drive a rock slope from *A* to *B*, starting from the main heading, when the position of the seam beyond the fault has been determined. The coal from beyond the fault can then be hoisted through this rock slope and hauled out of the mine. I submit this, hoping that it may be of some assistance in solving the problem.

E. D. Reynolds, Pres.,
West Blocton, Ala. Blocton Mining Company.

Americanizing the Foreigner

Letter No. 7—It was with peculiar interest that I read the letter of "Optimist," which appeared in *Coal Age*, Aug. 29, p. 415, and has since been followed by others. Many of the statements made in these letters, however, are so wide of my own experience that I cannot resist the desire to comment on a few of them. Certainly the conditions that have led writers to look upon the situation in hand so hopefully are quite different from those it has been my fortune to meet.

In the letter to which I first referred, "Optimist" suggests: "Let the teachers be instructed by mine officials to maintain a high standard of order and cleanliness in the schools." Think of applying this remark to the conditions existing in this state, where the teachers sent by the County school board to the different coal fields throughout the county are not usually the kind of whom much can be expected in the way of setting "a high standard."

Graduates of Graded Schools Sent as Teachers

For example, among the teachers sent out last year were young girls of 18 or 19 years, graduates of graded schools only, who were frequently heard to use such expressions as "them shoes," "have saw," and many others showing a like deficiency in their knowledge of English grammar. Also, for the most part, these girls dressed slovenly and appeared to care little for the work of which they were given charge, their chief

interest being the small salary that they received monthly.

If coal operators look for improvement to come through the work of these teachers and hope that the high standard of living they set before the children will have its influence on the foreign parents and boarders in that community, I fear they will have many, many years to wait before their hopes will be realized.

It may be asked, "Cannot the operators employ a better class of teachers?" Unfortunately, the answer is, "No!" And I must add that few of the companies have any influence with the school board to induce them to send more capable teachers. The idea seems to prevail on the board that the girls sent are good enough for the children they must teach.

Arbitrary Action of County School Board Obstructs School Work

Only last winter, our general manager asked permission of the school board to reroof the school building, at the company's expense. Although the roof was in very bad condition at the time, the board denied the request, stating that a committee attended to that business and it was their duty to advertise for bids before anything could be done. The general manager, however, went ahead and had the roof repaired, and the school started in September.

But, after the school opened, it was the middle of October or the first of November before the books arrived for the use of the children. It is needless to say that, while waiting for the books, little was accomplished although the school was in session every day. There is no truant officer here, and the usual reply to the teacher's inquiry as to a child's absence is, "What's the use of his going to school, he isn't learning anything."

In this camp of 3000 inhabitants, "Optimist's" suggestion that the company doctor could assist in securing clean and sanitary conditions is likewise wide of the mark. The patients, here, will not even carry out the doctor's instructions, unless it pleases them to do so. Last fall, when there was an epidemic of smallpox on this creek, it was impossible to quarantine the people in the houses where the disease prevailed.

Betterment Work More Successful as Aim of Workers is Understood

Speaking about "uplifting" the foreign-born miner another writer, in *Coal Age*, July 25, p. 190, suggests, "Among the employees of every large coal operation there should be a set of men who would act as missionaires of patriotic zeal among the foreign workers, in and out of the mine." Let me say that, in practically every coal camp where I have been located, until lately, I have failed to find one in twenty of the foreigners that did not think that the company officials were trying to beat them.

This condition, however, has changed considerably within the past year or so. Many foreign miners are now joining our lodges, and it is not uncommon to find them playing pool with the office men and other mine officials, with whom they are becoming acquainted. Nevertheless, they still resent the efforts of anyone to uplift them, as they call it.

In contrasting the foreign-born with the American miner, reference has been made to the latter's habits of thrift. In justice to the foreigner in West Virginia, let me say that he is, as a rule, more economical and manages to save more money than the American miner. The latter has usually spent everything and has nothing to draw when payday comes around, but that is not the case with the foreign miner, who generally carries off a fat envelope. Again, it is seldom that a foreign miner leaves town without first settling up what he owes, but this cannot be said of many American miners who would leave the company in debt, if possible.

Red-Cross Chapter Organized in Camp

Of all the efforts that have been put forth in behalf of our foreign miners, probably none have been more successful than those of the Red Cross. Only last year, the wife of the general manager of our company organized an auxiliary chapter of the Red Cross Society in our capital city. A wonderful work has since been accomplished through her efforts.

At first, the women were very reticent in regard to joining, fearing that the company was trying to swindle them out of their money; but time told the story, and these women were taught to make hospital garments and to knit. The head of the chapter went to the schools and told the children that she would meet them in the church every afternoon at 4 o'clock and teach them to knit. In about five months, the children were knitting sweaters for the Red Cross, and their little sisters who were too young to attend school were learning to knit also.

As the result of this woman's work, several hundred dollars were secured in a recent Red-Cross drive; and, on Sunday, from 75 to 100 people attend the church services, instead of 10 or 15, as formerly. Recently, the miners held a festival and other entertainments, in coöperation with the office and store men and realized a good profit for the benefit of the Red-Cross fund.

Results Shown by the General Improvement

Perhaps, one of the greatest benefits resulting from the Red-Cross work, is the fact that school teachers have been secured this year who promise better than ever before. To encourage them, the general manager has given them a cottage where they can all live together. There is, now, hearty coöperation on the part of the parents to make the school year a successful one.

Another noticeable feature is the pride that the women are now taking in their dress and personal appearance. Thrift and good-will is in evidence everywhere. The children are buying War-Saving and Thrift Stamps, as well as the grown-ups. The miners are more industrious and compartively few are leaving the camp. A short time ago a miner asked me to lend him a novel, and when he returned it he asked for another. A year ago that miner would not have read a book if I had given him one; much less would he have come to me to borrow one.

Last spring the company installed shower baths in the electric shop, and the miners were privileged to use them, for a small monthly fee. These baths are now a real pleasure to the men and there is a notice-

able improvement in their appearance and dress. Also, the company has furnished and equipped a children's playground, in front of the company store. This has been a source of pleasure to the children of the camp, and the evening usually finds many grown-up people participating in the fun. It is my belief that the Red-Cross and the war work deserve a large portion of the credit of Americanizing the foreigner in this district.

A READER.

Huntington, W. Va.

Justice to the Miner

Letter No. 9—Following the discussion in regard to justice to the miner, I notice that many persons are loud in their praises and comment freely on the conditions existing in miners' homes and in the camps; but little is said to inform the public on conditions under which many miners work in the mine.

The remark is often made, "Oh, yes, ——— Camp is a fine place in which to live; but I wouldn't work in the mine there, because I can make more money at the place over the hill. Over there, they pay the same price for loading coal in a 12-ft. seam as they pay here, where the seam is only 5 ft. thick and the miner is compelled to brush roof and move rock, with no compensation for the extra work he performs. Over there, the men do not have to push their cars in and out of the rooms; but, what is even more, the treatment they all receive from the mine foreman goes far to make them like the place."

ATTITUDE OF THE COLORADO FUEL AND IRON CO.

Such remarks as those just quoted show the great difference in mines operating in the same district, but under different management. I was glad to read the letter of E. H. Weitzel, manager Colorado Fuel and Iron Co., which appeared in *Coal Age*, Oct. 17, p. 753, pointing out the privileges the miners of that company enjoy, in spending their spare moments in profitable reading, bowling, or playing pool and billiards in the miners' club house operated by the Y. M. C. A.

However, it goes without saying that those miners could not profit by the opportunities afforded them if it were not for the good wages they are able to earn, under the company's management. The miner pays 50c. a month for his membership in the Y. M. C. A., and the same amount for the use of the bath house, to say nothing of the extra expense for ice cream, "near beer," pool and billiards, etc., for which the charges are the same as asked elsewhere.

The miners of the Colorado Fuel and Iron Co. are proud of their club house, and their wives and children go to church and school better dressed, since the saloons were moved off the premises. It can be truthfully said that if the company never did another thing to improve the conditions surrounding their miners, they deserve the highest praise for that one act. The driving out of the saloon from the camp has largely increased the purchase of Liberty Bonds and War-Savings and Thrift Stamps, by the miners. I would to God that the saloon had been made to go long years before.

Another great step forward was the acceptance, a few years ago, by this company, of the Rockefeller Industrial Representation Plan. Personally, I consider this the greatest plan ever devised, in respect to the relations of labor, capital and the public. It is only through such a plan that the coal miner will ever get justice of the kind and quality that he deserves. The plan is in keeping with the great principles of democracy, for which the world has been fighting, today. It guarantees to the individual the right to life, liberty and happiness.

The plan combats the principles of labor leaders, who believe that it is possible for miners to get justice only through lockouts, suspensions and strikes. It teaches the broad principle that if a miner is willing to give his employer all that the latter can rightfully expect, he must not be compelled to demand more for himself, by reason of a pledged allegiance to his fellow workers, who may claim that he should receive more.

In accepting the Rockefeller Industrial Plan, the company are paying their miners, today, more wages than ever before. But, this is not all; they are pledged to pay the same wages that may be paid to any miners in the same competitive field. It is not strange that the miners working for this company appear to be enjoying life.

PRACTICAL OPERATION OF THE ROCKEFELLER INDUSTRIAL PLAN IN COAL MINING

Almost without exception, the miners of the Colorado Fuel and Iron Co. are working steady, have plenty to eat, wear fine clothes, and live in beautiful homes, with pleasant and sanitary surroundings. In fact, they have everything that is worth while. That is the kind and quality of justice one wants to see the miner receive. Under the Rockefeller plan, he is guaranteed the full freedom of a personal manhood, and the same is accorded to womanhood. There is the right to enjoy and develop every opportunity, personal traits of character, freedom of speech and the education of their children.

Such privileges Americanize the foreigner rapidly. All have the freedom to go where they please and to spend their money when, where and as they wish, the only requirement being that they shall obey the laws, rules and regulations of the company, which are common to every well-regulated mining camp in this country. There is guaranteed to every man the right to perform his work unmolested by any individual or set of individuals whose purpose may be to create trouble, strife and discontent.

The influences that have surrounded the miner, through his allegiance to labor organizations, are the evidences of the power of the almighty dollar. Take away the salaries of labor leaders and labor unions would cease to exist. Instead, miners would be organized under a plan similar to that to which I have alluded.

The Rockefeller plan has shown to the world that capital and labor are mutually dependent on each other. The one cannot exist without the other. Their interests are common. When the operator and the miner, representing capital and labor, respectively, clasp hands and are willing to work for higher standards of living, involving their economic, social and spiritual welfare, then justice to the miner will be a reality and justice to the operator will, likewise, be assured.

Farr, Colo. JUSTICE.

INQUIRIES OF GENERAL INTEREST

Direct-Connected and Geared Hoisting Engines

We are hoisting cars at our slope with a 22 x 30-in. first-motion engine. With a steam pressure of 100 lb. per sq. in., the engine makes 50 r.p.m. and hoists the cars at the rate of 1000 ft. per minute.

It is now proposed to change this engine over to a shaft and put in its place a 16 x 24-in. second-motion engine, which is geared $2\frac{1}{2}$: 1 and runs at a speed of 125 r.p.m. I want to ask what effect the gearing has on the horsepower of an engine. Kindly explain the rule for calculating the horsepower of an engine and state how one can determine whether a certain size of geared engine will pull a certain load at a certain speed.

Greensburg, Penn. MINE ENGINEER.

From the data given, it is impossible to determine whether the geared engine will perform the same work as the larger first-motion engine now doing service at the slope, and which it is desired to use at the shaft opening.

The horsepower developed in an engine cylinder is equal to the total pressure of steam acting on the piston multiplied by the piston speed and divided by 33,000. To find the total pressure on the piston it is necessary to multiply the area of the cylinder by the mean effective steam pressure, which must either be taken from the engine card or calculated from the cutoff of the engine. Assuming an initial pressure in the cylinder of 100 lb. per sq.in. and a $\frac{3}{4}$ cutoff, the mean effective pressure in a steam cylinder, at sea level, will be practically 80 lb. per square inch.

The diameter of the cylinder of the first-motion engine, in this case, is 22 in. and its stroke 30 in. ($2\frac{1}{2}$ ft.). The area of a 22-in. cylinder is $0.7854 \times 22^2 =$ say 380 sq.in. The total average pressure of the cylinder throughout the stroke is therefore $80 \times 380 = 30{,}400$ lb. At a speed of 50 r.p.m., the engine makes 100 strokes per minute and has a piston speed of $100 \times 2\frac{1}{2} = 250$ ft. per min. The efficiency of a good direct-connected slide-valve engine can be taken as 85 or 90 per cent. The estimated horsepower exerted by this engine is therefore

$$H = \frac{0.85 \times 30{,}400 \times 250}{33{,}000} = \text{say } 200 \text{ hp.}$$

The smaller geared engine mentioned has a 16-in. cylinder and a 24-in. (2-ft.) stroke and, running at a speed of 125 r.p.m., makes 250 strokes per minute. The area of the cylinder is $0.7854 \times 16^2 =$ say 201 sq.in. Assuming the same mean effective pressure in the cylinder as before, the total average pressure on the piston is $80 \times 201 = 16{,}080$ lb. For a 2-ft. stroke the piston speed is $2 \times 250 = 500$ ft. per minute. The efficiency of a geared engine will be somewhat less than that of a direct-connected engine when operating under the same conditions and may be assumed, in this case, as 80 per cent. The horsepower developed by this geared engine is therefore

$$H = \frac{0.80 \times 16{,}080 \times 500}{33{,}000} = \text{say } 200 \text{ hp.}$$

These calculations show that the two engines have practically the same power. The fact that an engine is geared does not affect its power, except to slightly reduce the efficiency of the engine. No data are given to enable one to determine the speed of winding on the slope, which is stated at 1000 ft. per minute.

Waterproofing Cement Work

I want to ask a question regarding the effect of surface drainage on the concrete floor of a building. The floor is 42 ft. long and 24 ft. wide, and the concrete is 5 in. thick without any reinforcement. Although this floor is sunk 2 ft. below the surface of the ground, no provision is made for drainage. The foundation walls are 8 in. thick, and have no reinforcement.

At the side of the building and 25 ft. distant is a roadway that is being graded 24 in. deep and 25 ft. wide, the excavation being filled in with cinders. I want to ask if the surface drainage would have any effect to lift or break the concrete floor in the building. The concrete is a 1:2:4 mixture of good cement, sand and limestone rock broken to pass through a 1-in. mesh. One pound of waterproofing is added to each concrete mixture.

Staunton, Ill. A. C. G.

The real meaning of this inquiry is not clear. When laying a concrete floor in a basement, or at a lower level than the surface of the ground, provision should always be made for drainage. The concrete should be laid on 10 or 12 in. of well-rammed cinders, beneath which tile drain should be laid to carry off any water that may accumulate.

There is no need of any reinforcement in such a concrete floor. In the case mentioned, there would be no tendency of surface water to lift the concrete, if suitable provision is made against the action of frost. The outer walls of the building should be suitably reinforced. This inquiry, however, suggests the importance of waterproofing all cement work, which is always porous and absorbs water with the result that the concrete is disintegrated and weakened continually by the dissolving action of the water and by frost.

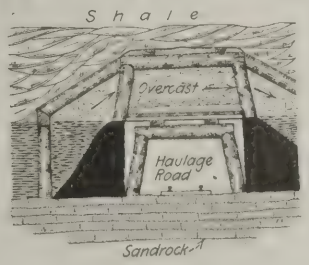
The waterproofing of cement structures has been carefully investigated by engineers, who have found that the most effective method is to impregnate the concrete mixture with oil whereby the absorption of water is prevented and the life of the concrete preserved. The application of gasoline in which from 5 to 10 per cent. of paraffin wax has been dissolved is recommended. The fluid can be applied to a concrete surface by a brush or sprayed over it with a handpump.

EXAMINATION QUESTIONS

Mine Examiners' Examination, Springfield, Ill., 1918

(Selected Questions)

Ques.—What should be the quantity of air at the downcast, to ventilate a mine employing 675 men and 22 mules?



Ans.—Assuming that this mine generates no gas and allowing 100 cu.ft. per minute for each man and 500 cu.ft. per minute for each mule, employed in the mine, the total quantity of air in circulation should be $675 \times 100 + 22 \times 500 = 78{,}500$ cu.ft. per minute.

Ques.—What is a door, stopping, brattice and overcast and what is each used for?

Ans.—A "door," in a mine, is a swinging partition placed in an entry or passageway, to deflect the air current into a crossheading or room. A "stopping" is a solid wall or partition built in a heading, crosscut or other passage to prevent the flow of air through such opening. A "brattice" is a partition built in an airway and consists of boards or canvas nailed to a line of posts set in the passage. Its purpose is to conduct the air current forward to the face and cause it to return on the other side of the brattice. The term "brattice" is sometimes incorrectly applied to a stopping.

An "overcast" is an air bridge built over a haulage road or other passageway, for the purpose of conducting a current of air across such entry or roadway. An overcast built at the mouth of a pair of cross-entries makes it possible to ventilate those entries without the use of a door, which is a particular advantage in the ventilation of a mine.

Ques.—Make a sketch showing how you would construct an overcast. How much air would pass through the same, it being 6 ft. high and 8 ft. wide, and the velocity being 600 ft. per min.?

Ans.—The accompanying figure shows a common form of overcast or air bridge built over a haulage road. Taking the dimensions of the overcast as given, its sectional area is $6 \times 8 = 48$ sq.ft. The velocity of the air current being 600 ft. per min., the volume of air passing is $600 \times 48 = 28{,}800$ cu.ft. per min.

Ques.—Is there a limit to the splitting of the air current?

Ans.—Yes, when an air current is divided too often, the velocity of the air is so reduced that it will not sweep away the gases lodged in the cavities of the roof and other void places in the mines. In order to move these gases, and drive them out of their lodging places, the air current must have the velocity required to effect that purpose. Methane or marsh gas lodged at the face of a pitch or in a cavity of the roof; and carbon dioxide or blackdamp, at the face of a dip, or in a swag or other low place, are difficult to move and require a considerable velocity of the air current.

Under ordinary mining conditions, the velocity of the air passing the working faces should not fall below 4 ft. a sec., and where gas is generated in the mine, the velocity should be from 4 to 6 ft. a sec., depending on the quantity of gas given off at the face. Therefore, in answer to the question asked, the limit to splitting may be said to be reached when the velocity of the air current at the working face in any district falls below the amounts just stated.

Ques.—What is a water gage, anemometer, safety lamp and barometer?

Ans.—A water gage is a device for measuring the difference of pressure between the intake and return airways in mines. It consists of a glass tube bent in the shape of the letter U. Both ends of the tube are open, one end being extended and bent at right angles so that it can be inserted through a hole in the partition dividing the two airways. When in position for use one end of the tube is open to the greater pressure of the intake airway while the other end is open to that of the return air. The difference of pressure, or the pressure causing the circulation inby of the point of observation, is then measured by the difference of the water level in the two tubes. One inch of water column indicates a pressure of 5.2 lb. per sq.ft. of sectional area in the airway.

An anemometer is an instrument used to measure the velocity of the air current in an airway. It consists of a vane having inclined blades so that the passing air rotates the vane. The instrument is so calibrated that one revolution of the vane corresponds to a velocity of 1 ft. per min. of the air current. In use, the instrument is exposed to the air current for one or more minutes, as timed by the watch, and the number of revolutions of the vane is read from the dial on the instrument.

A safety lamp, in mining practice, is a lamp in which the flame is inclosed in a chimney of glass and wire gauze, in such a manner that it is isolated from the outside atmosphere, which is fed into the lamp through gauge-protected openings, while the burnt air and gases pass out through the top of the gauze chimney.

The barometer is an instrument for measuring the atmospheric pressure. The mercurial barometer consists of a glass tube about 3 ft. in length, closed at one end and filled with mercury. When the tube is then inverted and the open end submerged in a vessel of mercury, the mercury column in the tube falls to a height corresponding to the pressure of the atmosphere acting on the surface of the mercury in the vessel below. Since 1 cu.in. of mercury weighs, practically, $\frac{1}{2}$ lb., a mercury column 30 in. in height corresponds to an atmospheric pressure of $30 \times \frac{1}{2} = 15$ lb. per sq. in.

COAL AND COKE NEWS

Harrisburg, Penn.

Anthracite production is falling below last year's output, and it is understood that the Fuel Administration is on the verge of sending one of its headquarters men to the hard coal region to establish an office here and take steps to stimulate mining, if possible. The region will probably be districted, each district to be assigned its quota of hard coal production, honors to be publicly awarded those districts which measure up to the standards fixed. It is learned unofficially that James B. Neale will be sent to the region. His headquarters will be either at Pottsville or Hazleton.

December has not brought the customary suspension of river coal-dredging operations on the Susquehanna and even on the Swatara, the Wiconisco and other streams in the anthracite field which carry down the small coal from the mines. Men and dredges are at work getting out the fine coal which is proving such an important addition to the supply of coal for industries and even for homes. As far down as Middletown dredges are working, and some of the boats will be kept at the harvest until the cold weather makes work on the streams hazardous. There have been more dredges and flats working this year than ever known before.

The Bureau of the Scranton Board of Trade has finally accepted the mine-cave proposal made by the coal companies operating in Scranton and Dunmore, but no agreement has been reached on the appointment of the three commissioners who will have charge of the work to see that the coal companies and the city carry out their part of the mine-cave agreement. The Scranton Surface Protective Association will ignore the mine-cave proposal entered into by the Board of Trade and the coal companies, and devote its energies to securing legislation at the coming session of that body.

Uniontown, Penn.

After having dropped steadily from 750,000 tons for the week ended Oct. 12 to 523,721 tons for the week ended Nov. 23, production of coal in the Connellsville region attained an output of 574,729 tons for the week ended Nov. 30. There is now every indication that influenza has done its worst damage in this region, but several weeks will be required before its effects entirely disappear.

A gratifying increase of 36,242 tons was shown in the shipments of byproduct coal in the weekly review of the fuel administration. Plants have been hard pressed during the last two weeks and have been clamoring insistently for coal. Coke output is placed at 255,127 tons, an increase of 15,177 over that of last week. The byproduct coal shipments for the week were 182,038 tons.

The Fuel Administration has discontinued the practice of commandeering coke tonnage, notice having been received by producers to the effect that they were at once more at liberty to dispose of their product to the best advantage. That phase of fuel administration activities in the Connellsville region since last March has been handled by C. E. Lenhart, district representative. The discontinuance of commandeering of coke will not have any effect upon prices. Neither is it believed will any disturbance in market conditions result. The demand for coke is still marked and is growing stronger. The decrease in production due to influenza and other causes will also react to stiffen the market and further increase the demand.

Charleston, W. Va.

New outbreaks of influenza in various parts of the Fairmont district are restricting the output of coal. There has been and is now no paucity of cars furnished the mines. During most of the week ending Nov. 30 the daily supply of cars averaged in the neighborhood of 1500, and few mines were closed down. Prompt deliveries of empties have also been of material benefit to the mines. The demand for Fairmont coal is far from being moribund.

Steady increases mark the mining operations in the Logan district, the latest report showing a total tonnage of 216,336, which represents 83 per cent. of the full time capacity, the production loss thus being only 17 per cent., 9.36 per cent. of which was due to labor shortage as against 14.60 per cent. for the previous week. The increase amounted to about 8000 tons. Car shortage about doubled, but caused a tonnage loss of only 4275 tons.

Although output in the Kanawha district is from 50,000 to 70,000 tons lower than the record production, still the mines are producing as much coal as could reasonably be expected. Virtually all coal produced has a market, and orders are sufficient to insure continued production at the present or a higher rate. There has been noticeable increase in the demand for Kanawha coal, Kanawha & Michigan mines being zoned out of certain Western territory in which there is a call for their coal. Exporters of coal from the Kanawha district, while experiencing no difficulty in securing orders, are having trouble in securing boats.

As has been the case all along—even during the war—labor leaders in the New River district, or rather a few of them, cause a good deal of unrest among miners which reacts on operations. Aside from that operators of the New River district are satisfied with conditions existing at present and believe prospects for an enlarged business are excellent. A decrease of 13,000 gross tons during the last week of November as compared with the previous week was due to the observance of Thanksgiving. The output for the week ending Nov. 23 was 247,000 gross tons and for the following week 233,193 gross tons.

Production in the Pocahontas and Tug River district is now nearly up to the high point reached during the progress of the war. Latest figures show the output to have jumped from 415,000 to 428,000 tons. More man power is now available. No surplus of the coal mined is accumulating in the Pocahontas region, there being a ready demand for all Pocahontas coal produced. Production of coke amounted to 50,495 tons.

With 24 mines in the Kanawha district not reporting, the total output for the week ending Nov. 30 was 151,764 tons. On its face that would indicate a loss of 6000 tons, but it is believed that if the mines out had reported there would have been an increase. Such tonnage loss as there was due to a labor shortage and to the Thanksgiving holiday, 1299 hours being recorded as the time lost through labor shortage. Cars furnished were sufficient to meet all requirements.

Victoria, B. C.

A blowout of coal and gas occurred recently at No. 1 East Mine, Coal Creek, Crowsnest Pass Collieries, Ltd. All men were withdrawn safely. This incident, taking place with the single-shift system in operation, is taken by those who have contended that the change would bring no improvement in conditions in respect of safety, as confirmation of their stand. Shortly before the happening mentioned above a fire threatened No. 1 South Mine, Coal Creek. It was confined, however, to a crosscut, being got under control before much damage had been done.

It is reported that coal output for British Columbia during the month of November is expected to show a decline in comparison with that of October, which was 217,482 tons. Both the Canadian Western Fuel Co. and the Canadian Collieries (D), Ltd., the largest producers of Vancouver Island, were seriously hampered by illness in the course of the past thirty-odd days. At one time there were as many as 600 of the employees of the Canadian Collieries away from work for periods of varying length. The same condition prevailed in the Nicola-Princeton and the Crowsnest Pass fields, so that it is felt that the figures which shortly will come to hand cannot be expected to be as satisfactory as hoped for. It is gratifying, however, to be able to report that normal conditions have returned and the collieries are producing at the same average pace as in October and previous months. December, therefore, should see between 200,000 and 250,000 tons of coal produced in the Province.

PENNSYLVANIA

Anthracite

Scranton—What threatened for a while to be a most disastrous fire broke out on Dec. 3 in the carpenter shop of the Mt. Pleasant colliery of the Scranton Coal Co. The structure was leveled to the ground and much of the machinery has been ruined. The shop was situated only a few feet from the boiler house and about 150 feet from the breaker, which for awhile seemed to be in imminent danger of destruction.

Shenandoah—On Nov. 30 a fire which threatened the valuable breaker and other outside buildings, destroyed the large boiler house of the Kehley Run colliery. The buildings were only saved by the heroic work of the volunteers. If the fire had succeeded in reaching the breaker and the other buildings 1200 men and boys would have been thrown idle. The daily production of the colliery is 2000 tons.

Wilkes-Barre—Lehigh Valley Coal Co. monthly employees will get $10 to $20 more under the announcement made of a wage raise to the persons not benefited by the recent agreement with the miners. Other coal companies will also advance their men.

Kingston—Miners employed at the No. 5 mine of the Delaware & Hudson Coal Co., at Larksville, went out on strike Nov. 30. They allege discrimination. About 500 men and boys are affected.

Price Hill—Production at the Price Hill plant of the Price Hill Colliery Co. has been materially increased by the installation of electrical machinery. The main entry has been relayed with heavy steel. A number of new houses have been built and others are under way. H. H. Pinkey is the superintendent at this plant.

Bituminous

Burgettstown—Roberts & Schaefer Co. have been awarded a contract for a Marcus screen to be installed in the new tipple at the Patterson mine of the Burgettstown Coal Co.

Uniontown—Fire of unknown origin destroyed the boiler house of the Brownsville Coal Co. on Nov. 30, causing a loss of $10,000. Forty men at the boiler house were thrown out of employment.

Pittsburgh—The Clinton Block Coal Co. is proceeding with the construction work in connection with a stripping mine at Imperial, and has contracted with the Roberts & Schaefer Co. for the installation of dump house, retarding conveyor, and tipple, which will include a Marcus picking table screen.

Clearfield—Herman Carlotti, a member of the executive board of district No. 2, United Mine Workers, who was appointed to look into the charges of profiteering at Wishaw, Jefferson County, during the epidemic of influenza at that place, has completed his investigation and will lay his findings before the next meeting of the executive committee at Clearfield. It is said that some of the physicians charge the miners as high as $20 for administering the preventive injection to a family of four, and that there are numerous instances of exorbitant charges for services rendered mine workers and their families.

WEST VIRGINIA

Macdonald—Provision has been made by the New River Co., managed by S. A. Scott, for enlarged power facilities. A stone power house is being constructed for its Cranberry plant. The company has also built at its Sprague plant a brick and concrete substation building which will house 2-kw. motor generator sets.

Lorentz—Electrical equipment will be installed by the Florence Coal Co. at its mines here with a view to increasing the tonnage of the plant. The company has erected a large number of houses for miners.

Charleston—The Big Bottom Coal Co., under the management of J. S. Cheyney, has begun to ship coal from its new operation on Campbell's Creek in the Kanawha field.

Cannelton—A shaft mine in the Eagle seam will be operated by the Cannelton Coal and Coke Co., of which F. O. Harris is general manager. The company is now engaged in sinking a shaft.

Coalwood—Construction work on the new Marcus tipple of the Carter Coal Co., at Olga mines, will proceed at an early date. The engineers, Roberts & Schaefer Co., have been given instructions to proceed with the installation of the tipple.

Macdonald—The Meadow Fork Fuel Co. is putting up a number of new houses at its Weeklow plant. The company has purchased and installed new equipment and is opening another drift mine. Operations had been suspended for about ten days owing to the prevalence of influenza. The Meadow Fork company is under the management of J. R. Charlton, of Macdonald.

ILLINOIS

Witt—The two large mines here operating under the receivership of T. C. Keller, of Chicago, have been closed down indefinitely and all tools and other material removed. The cause assigned is no market in which to sell the coal.

Herrin—The Chicago, Wilmington & Franklin Coal Co. is going to increase the daily output of its mine here from 2300 to 3000 tons. Methods to be employed are perfecting the roadway, timbering main haulage and putting in new rail bonds. Two General Electric motors are to be installed and six Jeffrey breast machines.

Johnson City—The Williamson County Coal Co. is making extensions to its plant. Two boilers and one 150-kw. generator have been installed, also two 7½-ton Goodman motors, four Goodman breast machines and 150 mine cars. The company has also built a new concrete machine shop and blacksmith shop combined. The cement gun is being used and is proving satisfactory.

MICHIGAN

Albion—The mine strike at the Albion coal mine is still unsettled at this writing. The men will not return to work until all their demands are met. The operators say they are in no hurry to come to terms. There is little demand for coal.

COLORADO

Pueblo—The Colorado Fuel and Iron Co. has contracted with the Roberts & Schaefer Co. for the installation of a Marcus tipple and rescreening plant, to be installed at the new Crested Butte operations.

Foreign News

Vancouver, B. C.—Replying to the suggestion recently made by the Vancouver city council that the Government should appoint a fuel controller for the province so that such municipalities as wished could license fuel dealers and have some supervision over them, Premier John Oliver has replied that the Government is preparing to name a fuel controller for British Columbia.

Munich—Bavaria is so short of industrial coal, according to latest advices received, that factories are closing daily and all may be compelled to shut down within a few weeks. This would add thousands of men without work to the large number of demobilized troops. The country is also short of food. The coal shortage is due to the French occupation of the Saar district. The entire Bohemian district is closed, and Silesia is unproductive owing to Polish troubles and disturbed transportation caused by the German retreat. There had been an almost rainless season, which rendered the water-power system useless and compelled the use of coal for the generating of electricity.

Victoria, B. C.—Chiefly because of the illness among miners, the dealers in the various cities of British Columbia state that they have not been able to obtain all the coal ordered during November, which has given rise to rumors of a fuel shortage. It just happened that difficulties at the collieries and the heaviest demand of the domestic trade synchronized, which situation is responsible for what uneasiness has been manifested by the general public. The operators point out that there is no danger of a famine and no reason for fear that any households will have to go cold. Coal, however, is retailing now at the highest figure since the exploitation of the Vancouver Island fields. Lump coal brings $10 a ton; nut, $9.75, and slack, $6.50. These prices at a point 80 miles from the mine are considered excessive by the consumers, but the operators and dealers point out that costs have doubled and that these quotations have been authorized by the fuel control department, which is an indication that they are justified by the conditions.

Personals

John R. Porter has been promoted from the position of superintendent of the Macdonald mines of the New River Co., to be assistant to General Manager S. A. Scott.

John Jones, of Plymouth, Penn., has been promoted to the position of superintendent of the mines of the West End Coal Co. Mr. Jones started his mining career as a breaker boy.

R. B. Isner, Elkins, W. Va., connected with the West Virginia Coal and Coke Co., has been appointed district representative of the Fairmont-Clarksburg district, effective Dec. 1, succeeding D. R. Lawson.

W. B. Plank, mining engineer of the United States Bureau of Mines, has been placed in charge of Bureau work in Alabama. He will have his headquarters at the Bureau's station at West End, Birmingham.

Rush Miller, superintendent of mines 36, 47 and 82, of the Consolidation Coal Co., has resigned. He will be succeeded by F. K. Day, who is now assistant production manager of the Fairmont district for the Federal Fuel Administration.

John Whitehead has been appointed superintendent of the Star Coal and Coke Co. at Red Star, W. Va., succeeding **J. M. Black**. Mr. Whitehead, until the present time, has been the superintendent of the Harvey and Prudence mines of the New River Company.

J. K. Mahaffey, who has been representing the Edison Storage Battery Co. in Washington in connection with government business, has been appointed as district sales manager of the Pittsburgh district. Mr. Mahaffey has been in the employ of the Edison Storage Battery Co. since 1916.

L. E. Schumacher, who for the past eight years has been chief inspector of the Westinghouse Electric and Manufacturing Co., at East Pittsburgh, Penn., has been promoted to works manager of the Krantz Manufacturing Co. of Brooklyn, N. Y., the latest subsidiary of the former company.

William Barrack, for a number of years superintendent of the New River-Pocahontas Coal Co.'s operations at Berwind, W. Va., has resigned to accept a similar position as superintendent of the Tidewater and King Coal companies at Vivian, these companies having been taken over, it is understood, by the Houston Collieries.

W. Guy Srodes, of Bellaire, Ohio, has resigned his position as assistant general manager of the George M. Jones interests (comprising the Ohio Collieries Co. in the Hocking Valley district and the Cambria Colliery Co. in eastern Ohio) effective Dec. 15, to accept the position of general superintendent of the Diamond Coal and Coke Co., at Pittsburgh, Penn.

Joseph E. McGowan, of Brooklyn, N. Y., has been elected a member of the Maryland Coal Co. of Maryland, and the Maryland Coal Co. of West Virginia, to succeed the late Howard S. Dickson. Mr. McGowan is secretary and treasurer of these two companies and of the Simpson Creek Coal Co., of which he is also a member of the board of directors, and of the Maryland Clay Products Co.

Bertram Smith, for the past three years district sales manager of the Detroit district of the Edison Storage Battery Co., has been appointed assistant general sales manager, with headquarters at the main office, Orange, N. J. Mr. Smith is known throughout the trade as one of the "old-timers" in the storage-battery business, having been active in the sale of lead batteries for many years before the advent of the alkaline storage batteries.

Obituary

Edwin L. Wade, traffic manager of the Carnegie Coal Co., Pittsburgh, Penn., died on Nov. 21, at his home in Midway, aged 26 years.

Harry Creighton, superintendent of the Maynard coal mines at Rutland, near Gallipolis, Ohio, was accidently killed on Nov. 25. Mr. Creighton was in his 49th year.

Clem Heck, one of the best known coal salesmen in Ohio and the Middle West, died at his home in this city recently from influenza. He spent a large portion of his time during the past year in Columbus and central Ohio, where he represented the M. A. Hanna Company.

A. J. Hill, a pioneer geologist and railway construction engineer of Canada, died on Nov. 26 at New Westminster, B. C. Early in his career Mr. Hill carried out a geological survey of the eastern Cape Breton coalfields, afterward embodied with the plans of the Dominion Geological Survey and published by order of the Government.

Anson S. Pollock, aged 33, well known mining engineer, died at his home in Monongahela City, Penn., on Nov. 9. Death was due to pneumonia following influenza. Mr. Pollock was superintendent for the Union Coal and Coke Co., and for several years had been mining engineer for the Pittsburgh-Buffalo Co. in Pittsburgh. He is survived by his widow and three small children, also by his father, James Pollock, superintendent of mines at Antrim, Penn.; two brothers, A. W. Pollock, manager of mines at Ramaye, W. Va., and James A. Pollock, of Harrisburg, Penn.; and four sisters.

Industrial News

Denver, Colo.—Effective Nov. 15, J. F. Emmert has been appointed sales manager of the Colony Coal Co., with coal mines at Dines, Wyo., and the Colorado and Utah Coal Co., with mines in Routt County, Colorado. Mr. Emmert will maintain offices in the First National Bank Building, Denver.

Toledo, Ohio—While the lake season is not yet over for the year 1918, still it is almost closed and records show a very prosperous season. The Hocking Valley docks loaded 5,132,482 tons up to Nov. 30, and it was estimated that there was about 30,000 tons yet to handle. The docks of that road loaded 4,830,000 tons during the entire season of 1917. The Toledo & Ohio Central docks ceased loading almost a week ago and the records show that 2,178,888 tons were loaded during the season as compared with 2,434,338 tons in 1917.

Philadelphia, Penn.—In order to relieve congestion on the lines of the Philadelphia & Reading Ry., the Government authorities have devised the plan of having that road turn over a heavy tonnage of bituminous coal to the Pennsylvania R.R. at Henderson Station, on the Chester Valley Branch. The Reading carries a heavy bituminous tonnage to tide at New York, but traffic has become so congested over the lines leading to that port that the present arrangement has been devised, the Pennsylvania R.R. turning the coal back to the Reading at Woodbourne, N. J., from which point the regular delivery is made.

Winnipeg, Man.—Four coal companies of Edmonton, Alta.—the Great West, Twin City, Edmonton Collieries and Humberstone Coal Co.—have become associated for the purpose of selling coal in Manitoba. They have incorporated under the name of the Alberta Coal Mines, Ltd., and established a yard in Winnipeg to handle their business. They have lately been shipping ten carloads per week, but are still lacking orders to keep them in full operation.

New York, N. Y.—Deprived of the right to do business by Fuel Administrator Garfield since June 19, the Penn Fuel Co. announced on Dec. 3 that its license had been restored upon the recommendation of the Department of Justice that no case had been found against it. It had been charged that the company had sold coal unsuited for use in the war zone for ships plying between the United States and neutral countries.

New York, N. Y.—In his annual report to the association on Monday, Dec. 9, Arthur F. Rice, Commissioner of the Coal Merchants' Association of New York, says that whatever may be said of other lines of business, the fact remains that Federal supervision of the coal trade has been the best thing that could have happened. The Government found a vital industry largely ignorant of the simplest principles of bookkeeping, and forced it to discover what those principles are; it discouraged unreasoning competition as disastrous to both buyer and the seller; it legislated into existence a "reasonable profit," which in many instances replaced a serious loss; and, by assuming the responsibility of making prices, it removed from the public mind the long existent suspicion that the retail coal business is a well-organized system of piracy. Incidentally, too, Mr. Rice says, it started a few concerns of questionable reputation along the straight and narrow path, by making it unsafe for them to continue in certain practices which had been highly detrimental to the retail dealers. Government control, Mr. Rice says, has given the dealers better business methods, removed public prejudice, and put a premium upon honesty; important changes, which naturally, could not be brought about in a short time without inflicting some inconvenience upon the dealers.

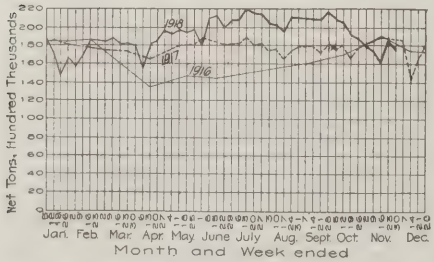
MARKET DEPARTMENT

Weekly Review

Bituminous Production Enough To Take Care of Current Needs—Many Mines Closed Down for Lack of Orders — Shortage of Gas Coals in Evidence—Anthracite Situation Shows Improvement

PRODUCTION of bituminous coal is ample for current requirements. Market conditions are not such as to favor full-time operations at many mines, and in fact the number of mines forced to close down because of no market is growing larger daily. This condition applies to mines in Illinois and other sections of the Middle West. Operators in the Standard field of Illinois are kept working only to satisfy the demand for railroad coal, though even the calls from this quarter are not what they should be. A number of cases are reported of operators in this field who are selling coal practically at the cost of production in order to get rid of their unbilled fuel.

In general, the possibility of any improvement in the bituminous market later on is restricted to special grades and to consumers who had been denied the use of coal while the country was at war. The southern Illinois field hopes for no relief until cold weather sets in, as almost every mine in the region has a surplus of coal on hand. Were it not for the railroad business, many more operations would have to close down on account of no orders.



Bituminous steam coals are plentiful. High-volatile coals, on the other hand, have shown such a falling off in production that gas companies which depend largely on this quality of coal are barely able to get enough to keep operating. The railroads, also, are making heavy drafts on these coals, and one of the results is the shortage for malleable iron plants and other industries requiring long-flame coals for special purposes. Several requisitions from Washington in favor of those using gas coals had to be disregarded. In spite of the great surplus of the ordinary steam grades of bituminous, there are plants shutting down for lack of gas coal.

Prices of bituminous are holding up pretty well at Government figures, though reductions are reported in a few quarters. In the endeavor to dispose of some of their stock retailers in St. Louis cut the price from 50c. to 75c. per ton, but the public evinced no great anxiety to buy. The same condition is true of the country generally. Buyers are waiting for a much greater drop in price and are consuming the coal they have accumulated. It is possible that a demand may come later on from buyers who will be anxious to get coals of better quality to use with the inferior fuel now piled in their bins.

Broken and pea make up the bulk of current shipments of anthracite, although egg has come up strongly during the past week, especially at the New York piers. Stove and chestnut, the two sizes most largely used by domestic consumers, are moving heavily on special requisitions through the Fuel Administration, and the lack of these sizes for ordinary distribution is still a great embarrassment to shippers and retailers. It is to be hoped that predictions of an easier supply later will be borne out by increased shipments in January, if not earlier. The fine weather we have been having has helped the domestic situation immeasurably.

WEEKLY COAL PRODUCTION

The improvement in bituminous production which occurred during the week of Nov. 23 failed to continue through the week of Nov. 30, the observance of Thanksgiving Day being the limiting factor. Preliminary estimates place production for the week of Nov. 30 at 9,710,000 net tons, a decrease compared with the week preceding of 1,280,000 net tons, or 11.7 per cent. Compared with the corresponding week of 1917, the decrease during the current week is estimated at 855,000 net tons, or 8 per cent. The average daily production per working day during the week of Nov. 30 (five and a half days), is estimated at 1,765,000 net tons as compared with 1,832,000 net tons during the week preceding and 1,921,000 net tons during Thanksgiving week of last year. The daily average for the coal year to date is estimated at 1,951,000 net tons as against the daily average of a similar period of 1917 of 1,765,000 net tons. The total production for the coal year to date is now estimated at 409,754,000 net tons as against 370,564,000 net tons during the same eight months of 1917.

The observance of Thanksgiving Day on Nov. 28 also caused a decrease of production of anthracite, estimates placing production during the week Nov. 30 at 1,613,000 net tons, as against 1,778,000 net tons during the week of Nov. 23 and as compared with 1,675,000 net tons during the week of Nov. 30, 1917. The daily average per working day during the current week is estimated at 293,000 net tons as compared with 324,000 net tons for the coal year to date and 331,000 net tons during a similar period of last year. For the coal year to date total production is estimated at 66,971,000 net tons and falls below the 1917 production by 1,648,000 net tons, or 2.5 per cent.

Reports from the carriers during the week ended Nov. 30 compared with the week preceding show a decrease in shipments from all districts with the exception of southwest Virginia. Compared with the corresponding week of 1917 the current week's shipments also fell below in all districts with the exception of Cumberland-Piedmont and Somerset, Fairmont and southwest Virginia district. For the coal year to date all districts still continue to report shipments in excess of last year.

Even though the lake season officially closed on Nov. 23, bituminous coal dumped at lower lake ports during the week ended Nov. 30 amounts to 239,891 net tons, bringing the total for the lake season, including vessel fuel, to 29, 289, 903 net tons.

Shipments of bituminous coal to New England during the week Nov. 30 amounting to 359,705 net tons and fell below the week of Nov. 23 by 52,671 net tons, or 13 per cent. Rail receipts through the gateways decreased approximately 10 per cent. and tidewater shipments a like amount. Northern harbors for the week report improvement while shipments from Hampton Roads decreased approximately 26 per cent.

Considerable falling off also occurred in Tidewater shipments during the week of Nov. 30, estimates placing the tonnage loaded at 648,455 net tons as compared with 753,843 net tons during the week preceding, or a decrease of 14 per cent. Baltimore was the lone harbor to report improvement during the week, while shipments from New York and Philadelphia decreased approximately 68,000 net tons, or 17 per cent., and from Hampton Roads, 47,000 net tons, or approximately 15 per cent.

The production of beehive coke in the United States during the week ended Nov. 30 is estimated at 522,000 net tons as compared with 521,000 net tons during the week ended Nov. 23 and 637,000 net tons during the correspondent week of 1917. The daily average during the current week is estimated at 87,000 net tons as compared with 106,000 net tons during the week of Nov. 30 of last year. The production during the past two weeks was the lowest reported since January of this year and is considerably lower than the weekly production of byproduct coke which is now averaging approximately 580,000 net tons per week. The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production of beehive coke at 291,972 net tons and the operation of their plants at 65.6 per cent. In these districts improvements occurred during the week in labor conditions. The same operators produced 160,500 net tons of coal.

The production of byproduct coke during the week of Nov. 30 is estimated at 572,494 net tons as compared with 574,847 net tons during the week preceding. During the current week the plants of the country were operated at 88 per cent of their full time and during the week preceding at 88.4 per cent. While repairs to plants remained the limiting factor, loss of full time attributed to no market increased during the week from 0.8 per cent to 1.8 per cent., such losses being reported by operators in two states, Massachusetts and Pennsylvania. A decrease in production occurred during the week ended Nov. 30 in Illinois, Indiana, Minnesota, Tennessee and West Virginia. In all states with the exception of Minnesota this decrease is attributed to repairs to plants, while in Minnesota other causes brought about the decline. No market losses in Massachusetts amounted to 37.3 per cent. of full time, and were

but slightly lower than those reported during the week preceding, while in Pennsylvania loss of time attributed to no market was offset by repaired plants. Improvement in operating conditions also occurred during the current week in Kentucky and Maryland. Pennsylvania operators alone now report loss of time on account of shortage of byproduct coal.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running about the same as for the corresponding week of 1917. Road sales for immediate delivery were even while sales for future delivery were not so heavy compared with same week last year. Not quite so many customers were in the house. Retailers report an excellent holiday business. Collections continue good.

American Wool and Cotton Reporter—There is no doubt of a sufficient supply of wool, although the grade may not always be exactly what particular manufacturers may desire. The supply can under no circumstances become less than needed, unless the Government prevents anything like resumption of normal conditions in the raw wool trade. No anxiety is exhibited by the South with the recent decline of the price of cotton. They are not pushing their cotton on the market at all. Southern planters and owners of the staple are holding their cotton until they get what they want.

Bradstreet's—Uncertainty, savored, however, with optimism, accompanied by a manifestly slower gait in actual movements and additional cancellations of war orders, epitimizes trade conditions. Groping for tangible tendencies, speculating as to the course of prices, shifting from war to peace work and year-end stock-taking occupy most attention in the larger lines. Underneath the pause, preparations to send salesmen on the road after the turn of the year are going on. Immediate demand, light as it is, overshadows buying for future account, thus indicating a disposition to await developments while covering current needs.

Dry Goods Economist—The principal activity of the week in retail dry goods and department stores has been centered upon the sale of holiday goods, and of needed cold weather wear. The stores in all principal centers have been thronged with customers, and sales have reached high averages. In view of the large volume of business being done, wholesalers and manufacturers have looked for liberal orders and reorders on goods needed for consumption in the near future. Instead, however, a feeling of conservatism has made itself felt in an unmistakable degree. Heads of departments in retail stores are anxious to dispose of goods purchased at high prices, and are not inclined to increase their holdings, because of a feeling that before additional goods are needed prices may undergo a revision downward.

Atlantic Seaboard

BOSTON

Market extremely dull. Inquiry all-rail confined to a few railroads and special requirements. No demand for steamers. Obscure prospect coastwise for Hampton Road shippers. Quiet market over New York piers. Improved demand for bunker coals. District representatives notified to cancel all requisitions in favor of industrials. Receipts continue to sag. High volatile grades again in short supply. Possibility of improved market later is restricted to requirements not able to stock during early fall, or those desiring better grades. Anthracite receipts fall off slightly. Shortage of stove and chestnut continues. Criticism of New England Fuel Administration for method of financing "free coal." Rumor that anthracite section will cease functioning during January. Mr. Storrow refuses Boston City Council demand for data as to retail profits.

Bituminous—The first week of the absence of local regulation was almost colorless. Except for a few forced sales of water-borne coal at rehandling points there have been no developments as to price and the market continues extremely dull. Empty coal cars are still accumulating and very light movement is the rule. Reserve supplies are far beyond normal and there is every inducement to use up the coal on hand before making further purchases. Not only is it higher in price than buyers expect to pay next season, but its nondescript character, in most instances, and the prospect if not the actual presence of fire in storage piles are important considerations in the fuel department of practically every industry in this territory. There is almost no spot market either all-rail or by water, and that shipper is fortunate who is still able to get shipments accepted even when in fulfillment of contract.

All-rail inquiry is confined closely to certain of the railroads, and to special requirements where arrangements were not made earlier. All the railroads are carrying liberal reserve stocks, but apparently on the part of some there is still a disposition to take rail coal at the present fixed price for a while longer rather than pick up coal from storage. A lot of the fuel in stock was accumulated on high prices from steamers where demurrage charges had accrued, and almost it would be supposed that such reserves would be worked off rather than to have purchases made under present conditions. On the other hand, rail coal cannot be had, even today, just for the asking. Influenza is still a factor in the region and there are enough local differences over the wage scale, etc., to make more than a few operators decline even the meager orders now being offered them. The railroads nearer the mines are also taking coal in greater quantities and the decreased volume to New England is not wholly due to lack of market.

Inquiry for coal over the New York piers is equally dull. Even coals from Pools 10 and 11 are not an easy sale for shipment along the Sound. Pool 10 was recently included among the grades suitable for bunkering purposes and it is expected that increased sailings overseas from New York will stimulate demand for the better coals. While just at this time there are very few ships to bunker, and the market is dull in consequence, the trade is confident this will improve. Indeed there are signs of this already, and when output is more nearly on a normal basis a much heavier movement to the piers will be looked for.

The Greensburg district, as well as other regions where the high volatile grades originate, has shown such a notable falling off in production that New England gas companies, for instance, are barely able to get supply enough for current operation. The railroads, also, are making heavy drafts on the current output of these coals and one of the results is the shortage for malleable iron plants and others requiring long flame coals for special purposes. Several requisitions from Washington in favor of industries of this kind have had to be disregarded, and today, in this territory, in spite of the great surplus in every direction of ordinary steam grades there are plants shutting down for lack of gas coal.

In general, therefore, the possibility of any improved market later is restricted to special grades and for requirements where there was less opportunity during August and September to accumulate coal. It is possible that there will also be inquiry later from buyers who will be anxious to get the coals of better quality to help use the inferior fuel that is now piled high in their bins.

Anthracite—The movement of domestic sizes through the gateways has again fallen off slightly. The daily average for November was 333 cars, but the first few days of December saw this figure reduced to only a little over 300 cars. Broken and pea still ke up the bulk of current shipments, both water and rail, although egg has come up strongly the last few days, particularly at the New York piers. Stove and chestnut are moving heavily on special requisitions ough the **Fuel Administration** and the lack of them for ordinary distribution is still a great embarrassment to shippers and retailers. As between different communities there has been great inequality of distribution if the two sizes most largely used, and it is to be hoped that predictions of an easier supply later will be borne out by increased shipments in January, if not earlier.

Mr. Storrow is being commended for his strong stand in answer to the demand of a committee of the Boston City Council for complete data with respect to the net profit of each Boston retail dealer on each ton sold. Mr. Storrow refused to give such information, on the ground that if it came to him it would be received by him as a Federal officer and one in no wise subject to the direction of the Boston City Cohncil. The fact that Mr. Storrow is a member of the Boston City Council lent some spice to the controversy.

NEW YORK

Demand for anthracite stove and chestnut continues to absorb shipments. Pea and the smaller coals plentiful. Shipments to this market far below requirements. Production hindered by lack of labor. Bituminous in good demand. Commercial coal supplies kept down by bunker requirements.

Anthracite—Increased receipts for the local trade and the continuation of favorable weather have put the anthracite market on a better footing. Dealers have not been urged to make deliveries and they have had a reasonable breathing spell. At the same time consumers have been permitted to go into the middle of December without scarcely touching their winter supply. While there are many who believe there is going to be a lack of domestic coals here all winter, those who are in a position to know do not expect any such conditions as existed last winter to arise this season. They do not look for any surplus of egg, stove or chestnut, but on the other hand do not look for any extreme shortage of these sizes.

With the demand in the Northwest taken care of and the shipments to these points practically stopped, more coal should come to eastern points.

In keeping with the past few weeks the cry is for egg, stove and chestnut sizes, but it appears there is less of these coals in the dealers' yards than for many months back. Broken and pea are in better supply, but the latter, which was plentiful a few weeks ago, is tightening. Consumers who are short of their usual quantity of the larger coals are being induced to take to burning pea, with the result that it is scarcer.

So far New York, with the exception of a few days, has not felt the effects of the winter and consequently comparatively little of its winter suppir of coal has been burned. Nearly every householder has plenty of coal on hand to last him for several weeks, and meantime, with western shipments curtailed and the situation in other sections of the country back from the seaboard in good shape, shipments to tidewater which were neglected earlier in the season will be increased and more coal will be rushed into this market.

State Fuel Administrator Cooke has announced some slight changes in the allotments of anthracite to various towns throughout the state, and has placed embargoes on shipments to numerous places.

The demand for No. 1 buckwheat has caused a tightening in that size and has caused a shortage in supply. Two of the selling agencies have announced an advance of 40c. per ton in their price for this size and a similar advance has been made by some individuals. So far no change in prices has been forthcoming from the large producers. No change in prices as to rice and barley have been announced, which sizes remain plentiful.

With encouraging reports from certain sections of the coal fields, showing better production, the dumpings at the local docks for the week ending Dec. 6 amounted to 6127 cars, as compared with 4869 cars the previous week.

In the northern coal fields producers report that influenza seems to have taken a fresh hold, and many new cases have been reported. In the southern fields conditions are slightly better.

Current quotations, per gross tons, f.o.b., Tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individual
Broken	$7.80	$8.55	Buck	$5.10	$5.90
Egg	7.70	8.45	Rice	4.65	5.10
Stove	7.95	8 70	Barley	4.15	4.30
Chestnut	8.05	8.80	Boiler	4.60	
Pea	6.55	7.30			

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—The general situation here shows a slight improvement. Commercial coals are not so much in evidence, due in a great measure to the inclusion of Pools 4 and 10 into the bunker class.

Production figures are showing a steady increase, with a corresponding falling off in demand by large consumers. Shipments to this port for the week ending Nov. 16, while showing a decrease of 184 cars from the figures of the preceding week, were sufficient to take care of current requirements inasmuch as the demand from New England water points has nearly ended for the season. This week will practically see the end of shipments of so-called "Storrow" coal from this port, and it is expected that all accounts for this coal will be closed within a few weeks.

There was an improvement shown in the local dumpings for the week ending Dec. 6, when 6450 cars were handled as against 6127 cars the previous week, an increase of 323 cars.

With the cancellation by the Fuel Administration of all requisitions for bituminous coal to industrial plants such industries will now be forced into the market for their supply, and shippers will have a better opportunity to dispose of their surplus as they see fit. This demand will not, however, be the means of forcing

a cut in prices unless weather conditions are such as to keep down consumption and thus create a long market. Producers do not anticipate any such conditions with the winter just starting, and a labor shortage.

The anticipated removal of price restrictions on bituminous which was to have become effective Dec. 15 is not expected to materialize. It was said among the trade that the latest information was that the Fuel Administration wiuld continue to have supervision over the industry until Apr. 1 at least, and that there would be no changes in prices. This was welcome news to many of the trade, who believe that the removal of restrictions at this time would not be beneficial.

Current quotations, based in Government prices at the mines, net ton f.o.b., tidewater at the lower ports, are as follows:

	Mine Gross	F.o.b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite conditions unsatisfactory. Conflicting instructions annoy. No delivery of entire orders prior to Jan. 1. Stove and nut still short, but improvement shown. Dealers' needs overstated? Speculating on future trade. Some salesmen out. Labor situation improved. Steam demand fair. Bituminous firmer. Good coals in strong demand. Tide business active.

Anthracite—Another week of most unsatisfactory business conditions in both branches of the trade is to be recorded. There are many cases where the relationship between the shipper and retailer is becoming strained, to put it mildly. The officials of the state and city fuel administrations are showing unmistakable signs of tiring of their positions, and it is understood there has been much friction of late with various interests. The sales agents in their efforts to pacify disgruntled buyers show a strong inclination to criticize the distribution.

Stove and chestnut are as scarce as ever, and the demand for these sizes increase each day. The largest shipping company is now making substantial daily consignments here, but as this trade has been almost neglected for six weeks it will be some time before any great improvement will show in the general condition. After unusual efforts and much pressure from their trade another company has just arranged to make up some of its deficiency in tonnage. The suburban dealers in the extreme northwestern section of the city have been the greatest sufferers, but they will undoubtedly receive attention this week. The trade in Germantown and Chestnut Hill, where the homes are much larger and the required tonnage much heavier, is also in urgent need and we expect soon to see some concerted action from them.

Notwithstanding the cry for coal from all directions it is apparent the opinion is growing that the trade will not require the heavy consignments they now claim are necessary. The unusually mild weather of fall and early winter saved thousands of tons and helped in the economy of coal that all consumers seem to be practicing.

We frequently hear the prospects of spring business discussed, for there are some in the trade who predict the present market will collapse in March. Yet there are others who state that the people have had it drilled into them so thoroughly to buy early, that those with the money will surely continue the practice of taking in their coal supply as soon as they can get it.

In speaking of the spring business, much conjecture is expressed as to the prices, and there are some who predict that the public will not buy coal next spring for the following winter's consumption, if only the usual reduction from the present high rates is offered. While such talk may be premature, it shows that both the shippers and the larger dealers are already looking ahead. As a matter of fact quite a few of the companies are now sending their salesmen out on the street. This is not because they have any coal to offer, but inasmuch as some of the former office workers are being released from the army, these concerns are taking advantage of the opportunity to let their salesmen go over their territories to get in closer touch with conditions, with future business in view.

Judging from the fact that during the recent scarcity of coal a number of dealers laid off help, we are inclined to believe the labor situation is much easier. Some months ago, whether yards were bare of coal or not, no retailer was willing to risk losing a yard man or driver by suspending him. In fact we know many who paid full wages when men failed to report for work for a day or two.

Pea coal seems to be fairly easy in most sections, but the dealers expect their rather small stocks to disappear with the first snow. As one dealer expresses it, his pea coal buyers are never heard from until the snow flies.

In the steam trade buckwheat is fairly strong, and rice is causing little concern. Barley is in bad shape and a great deal of it is being sent into the storage yards, while culm is practically unsalable.

Judging from the way all dealers pay their bills the retailers cannot be in the desperate shape they would like their shippers to believe. It would appear that the business was now on at least a 75 per cent. cash basis, and the advantages of this plan are so apparent that no one wants to go back to the old system of long credits and cut prices.

The agitation as to the retail prices has about subsided, and the public seem to have taken in good faith the statement of the fuel officials in regard to the reasons for the increase. Privately the dealers still feel they should be allowed some extra compensation, but this seems unlikely and it is believed the fuel administration will endeavor to hold them off until spring and then the market prices will be in effect with the retirement of the administration.

The prices per gross ton c.o.d. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—The market has grown appreciably stronger, particularly in high-volatile coals. There is an active demand for about all the coal that reaches here. The wagon-mine operators are still handicapped by the lack of box-car equipment. At Tide the demand for coal continues most active. It is generally agreed that the market is assuming a better tone, but there are some consumers who are actually refusing coal. These are the very large plants, many of which have been on Government work, and during the transition to normal activities they are cutting down their coal receipts, owing to heavy stocks already held by them.

There is a constant rumor that the fuel administration will relinquish all control of the bituminous situation by the first of the year. While no one anticipates any particular unsettling of trade, there is quite a good deal of speculation as to what the market will settle down to as to prices.

BALTIMORE

Bituminous situation remains easy, with demand comparatively light. More and more offers of fuel. Hard coal situation unsatisfactory and local fuel administration officials appeal for popular sizes.

Bituminous—Supplies of bituminous here seem to be adequate for the time being, and, as business firms have been taught not to stock up for months in advance, the demand that comes forward is apparently not urgent in most cases, industries being content to replenish when stocks run down. Purchasers are growing a little more discriminating, but this is met by the fact that a better grade of coal is also running, even though best fuels still remain under Government direction. Considerable quantities of good gas coal are now coming through, also, in connection with pier loadings. In a very short time also it is expected that a big jump will be noted in export movement of coal, and the trade as a whole is expecting that this will prove one means of preventing any big drop in price under competition.

Anthracite—The Maryland Fuel Administrator and members of his Baltimore City Committee have made an appeal by personal visit to the anthracite distributing committee in Philadelphia for relief of the situation in Baltimore. Not only is the total movement claimed to be below needs, but the fact that stove and nut sizes are not often included in the tonnage to a city that is made up in unusual amount of small homes is causing worry. Egg coal is not much used in many homes here that are now without coal. The zone rule against Sunbury was lifted and some stove coal of that quality has come through, but not enough to affect the general situation. This coal has always retailed here at 25c. above the schedule for white ash, and while the local administration has not allowed it placed on the formal schedule the majority of dealers here, to receive any Sunbury, are selling at the old advance over circular price for white ash. It is claimed that breakage makes this necessary.

Lake Markets

PITTSBURGH

Production increasing slowly. Market still firm for standard grades.

Coal production in the Pittsburgh district is increasing, but only very slowly. The influenza has been on the wane, so far as concerns news cases, but men are a long time returning to work and operators are encouraging them to make sure they are entirely recovered before they resume work. Car supply has improved and is almost entirely satisfactory.

Under instructions from the Federal Fuel Administration the local distributor is now taking care only of railroads and public utilities generally, ordinary private consumers being left to shift for themselves. This reduces the distribution control to about 45 per cent. of the total.

Consumers are showing no disposition to stock coal, even if afforded the opportunity, except the byproduct coke producers, and they will stock only their favorite grades, which are still difficult to secure. Much byproduct coke is being made with less admixture of Connellsville coal than is desired.

The Pittsburgh district coal market shows no signs of weakness as regards standard grades, and operators insist that the market is going to hold when price control is taken off. While there were intimations that the control would be taken off about Dec. 15, it is now far from certain that this will be done, by reason of the curtailment in output that has occurred. Wagon mines are still operating, but their production is off somewhat and it is doubtful whether many will operate clear through the winter. The market is quotable at Government limits as formerly, but brokers can rarely secure a commission from buyers in addition, Government prices being: Slack, $2.10; mine-run, $2.35; slack, $2.70; per net ton at mine, Pittsburgh district.

TORONTO

Shipments of anthracite light. Only grate and buckwheat procurable. Bituminous market quiet, owing to closing of munition plants. Labor shortage relieved. Fuel controller urges use of substitutes for hard coal.

Receipts of anthracite continue light and are practically confined to grate and buckwheat, local deliveries being restricted to these grades. With the closing down of many munition plants the general labor shortage has been greatly relieved, and coal dealers have now all the labor they need. The market for bituminous continues very quiet, owing to the lessened industrial demand, and dealers do not anticipate any change for the better until the munition manufacturers have reverted to, or engaged in, other branches of production, as most of them are preparing to do.

R. Home Smith, Provincial Fuel Controller, has issued another warning to the public, pointing out that the Province will be faced with a serious shortage before spring, as the cut in the supply will be considerably more than the 20 per cent. reduction in the allotment made by the United States Fuel Administration. In the distribution domestic users will be given the preference. Bituminous coal and wood must be substituted for anthracite in all buildings having furnaces in which they can be used, and owners of office buildings, apartment houses, warehouses and factories are required to sell their anthracite on hand and divert shipments not already received.

BUFFALO

Asking what the throwing off of restrictions will do for the bituminous trade, opinions differ. Trade dull. No anthracite increase. All going to lakes yet.

The surplus here of bituminous coal is still reported to be as large as ever, so that if production has suffered considerably the consumer is not disturbed by it. The general idea is that not only will the thin-vein Allegheny Valley coal lose its extra price, but that all other bituminous will have to come down also, for there is a large amount of Ohio coal to be disposed of in this market. It is not yet allowed to go east of Buffalo, but will soon

go free again. This market knows the coal and is ready to handle it once more.

Buffalo has suffered severely from the late shortage, as it did not control enough coal to meet the needs of the shippers here. Now, however, the conditions are changed and more coal is to be had than can be sold. On this account the jobbers are coming back to business again, though they find it poor.

Anthracite—The clamor for coal increases as the weather grows colder. From the reports one would think that nobody had any. Some of the distributors have the idea that the supply that has come in lately has not kept up with the consumption. The weather has done well by the trade of late, as not in a long time has there been so warm a fall. The best that the distributors can do now is to meet the most urgent cases till the supply increases after the lakes close.

CLEVELAND

Demand for No. 8 coal to mix with lower-grade fuel has come in surprising volume from consuming districts heretofore denied No. 8 coal under the zone system. This has offset to a great extent an otherwise narrowing market. Production again is severely feeling effects of influenza.

Bituminous—With zone barriers gradualy being broken down and the outlet for No. 8 coal broadened, a surprising demand has arisen in districts amply stocked with coal from other producing sections. Especially is this true of Michigan, which has absorbed a considerable amount of Indiana and Illinois coal. Regular No. 8 buyers intend mixing their preferred supplies with the coal forced upon them by the zoning system. This outlet has come just at the time steam-coal consumers in northern Ohio have entirely left the market and the lake season has practically come to an end.

Accordingly, with production badly off on account of influenza, demand for standard No. 8 coal is keeping right on the heels of the supply, and prices have held surprisingly firm. On this point operators and the local fuel administration officials are agreed. Very little regular No. 8 coal can be purchased below the Government prices, it is asserted, though stripping coal can be had at virtually the buyer's price. Concessions of 70c. on this coal to $1 are of frequent occurrence, but the takers are few. The railroads are again evidencing a desire to obtain a general reduction in the price of their fuel, but operators are not disposed to accommodate them.

Requests for cancellations of contracts have been more numerous. In the majority of cases they have been refused. Where an operator could divert the coal and the interest seeking cancellation is a friend, it has been done. But outside of contracts, practically no coal is moving into northern Ohio plants. This is more because of a desire to deplete stockpiles than a depression in production. The change from a war to a peace footing is being made quite painlessly in this district, due mainly to the large automobile and automobile parts industries, and the turn of the year undoubtedly will find steam coal again moving in fair volume. Recurrence of cold weather has stimulated domestic demand somewhat. Much coal is believed being lost in stockpile fires.

Anthracite — Receipts have increased slightly, while 2500 tons held by a factory in Cleveland for Government war work have been released. This has thrown more anthracite on the market, but it is not a drop in the bucket compared with what could be disposed of.

Lake Trade—Five cargoes of bituminous for Milwaukee have been loaded at Lake Erie ports and these, it is believed, will wind up the Great Lakes bituminous season. Anthracite will be loaded at Buffalo so long as the carriers are operated. The rate from Buffalo to Lake Michigan has been advanced to $1.

DETROIT

Steam plants and retail dealers, with an oversupply of coal, present a serious hindrance to normal business in bituminous. Anthracite continues short in supply.

Bituminous—Too much bituminous coal in yards of retail dealers and in the stockpiles of steam plants in and around Detroit is reflected in a greatly reduced volume of business for wholesalers and jobbers in the Detroit market. Both classes of buyers apparently took alarm at the predictions of impending coal shortage that were circulated a few weeks ago. Their efforts to guard against shortage seem to have produced an indiscriminate scramble for stock, in many cases, with the result that buyers took anything and everything offered.

Because of this haste, the retailers now find their yards congested with bituminous coal, much of which is mine-run and other forms of stock that the household consumers object to taking; while the steam plants are experiencing annoyance with coal of an inferior quality that was bought to fill out reserves when the more desirable stock from West Virginia and Ohio mines was withheld by the Fuel Administration's modified zone regulations.

Some of the retailers are endeavoring to dispose of excess stocks through sale to departments of the municipal government. The municipal purchasing agent informs them, however, that the price at which they offer coal to the city is about $1 a ton higher than he can buy bituminous coal elsewhere. There is said to be a possibility of the dealers being asked to submit bids for part of the city's supply.

Lake Trade—Shippers in Buffalo are still loading anthracite for movement up the lakes, and within the last few days have succeeded in chartering a dozen or more vessels. The carrying charge on coal from Buffalo to Milwaukee has been raised to $1 a ton, whil $1.15 a ton has been offered on cargoes to be taken from Buffalo to the head of Lake Superior.

COLUMBUS

The coal trade in Ohio is still rather weak, especially in the steam grades. Domestic business is slow because of unfavorable weather conditions. Producing and shipping interests are playing a waiting game.

The coal industry in Ohio is still rather quiet in all respects. There is a plentiful supply of all grades, but more especially mine-run and screenings. The demand is curtailed by the stoppage of hostilities and also because of the continued warm weather, which has not stimulated the domestic trade. The tone of the trade is not good and coal men are at a loss to judge the future. But it is generally conceded that there will be a better demand for all grades after the first of the year.

The steam trade is quiet to the extreme. Buying on the part of steam users is at a minimum because of rather large stocks in reserve and also because of uncertainty in the future. The Michigan market is closed temporarily because of the reserves of Indiana and Illinois coal. Steam users generally are loath to increase stocks under present conditions and are following the policy of using up what they have on hand. Railroads are very slow in taking tonnage and that has been one of the big departments of the trade for some time. The readjustment program is not yet mapped out and uncertainty pervades the market on all sides.

Domestic trade is slow, as retailers have ample stocks for the present. They have not yet been favored by cold weather and consequently have not been able to move any stocks. There is some demand for the so-called fancy grades, but dealers have little available storage space. Domestic prices are still firm at Government levels as it is realized that any reduction will not stimulate trade under present conditions. The differential between thick and thin vein Hocking has disappeared. Pocahontas is not yet on the market, but some is expected soon. New River and splints are coming in to a certain extent. The change in zones is expected to bring all former varieties that sold in Ohio.

Production has been reduced because of a lull in the demand and also because of the prevalence of the influenza epidemic. The output in the eastern Ohio field shows a reduction to about 40 per cent. of normal. In the Hocking Valley and Pomeroy Bend the output is about 40 per cent. and possibly less. Crooksville and Cambridge fields show up with about the same percentage.

CINCINNATI

The market is quiet, uncertainty regarding industrial prospects hampering demand. Supplies on hand are better than usual.

The process of changing from a war to a peace basis is proving so complicated, as far as the numerous industries in this section are concerned, that it has produced almost a complete standstill in some lines, and is affecting others hardly less. The cessation of manufacturing for war purposes has of course been complete, and while the Government may make adjustments to prevent losses among concerns which had contracts for the production of supplies, the supplies themselves will not be made except in a few instances. The result is that as peace business has not yet had time to make itself felt in the shape of definite orders, and as many plants must undergo some changes in order to turn them back to ordinary business, there is a considerable degree of industrial idleness, which is being reflected in an unusually small demand for fuel, considering the season. For the same reason, manufacturers are reluctant to commit themselves to contracts for fuel as long as they are uncertain as to what their requirements are going to be, and this uncertainty will persist until a change in the industrial situation has time to take place. The extent to which fuel has been stored by consumers of all classes has also undoubtedly had a strong influence on the situation, as domestic consumers are taken care of by storage to an unprecedented extent, while many manufacturers, who expected to operate on a war basis all winter, made correspondingly large preparations for the fuel supplies, including special provisions for yard storage. Production is not on a large scale, as operators see no reason to push things under the circumstances.

LOUISVILLE

Some small demand for better grades of domestic. Steam generally dull, with screenings in better demand than mine-run. Considerable effort shown to cancel contracts.

Reports from producers, jobbers and retailers this week are generally unsatisfactory. The market is weak, and the unscrupulous small operators, jobbers and retailers are cutting prices considerably under the Government price quotations. Many of them are virtually forced to do so in order to keep going. With no demand to speak of for better grade coals, and low grade coals not wanted, the situation is serious. Many retailers have heavy holdings of low grade coals, mine-run, etc., which were purchased on the strength of efforts made by the Fuel Administration, and in some cases these coals are expected to be hard to sell at anything like a fair price, considering the fact that prices are being cut on the low grades, and some of the retailers with high priced low grade coals on hand will have to sell at much lower than expected figures.

As a result of a smaller demand for coal in the Pittsburgh field, West Virginia and Pittsburgh bituminous coals are moving into the Cincinnati and Kentucky districts more freely; and indications are that a good boating stage will bring out a lot of river coal. However, the markets as far south as Cairo are well taken care of, excepting a few river towns which depend on river coal. However, if the packages and tows can be secured, there may be a fair southern market for it. However, western Kentucky is paying more and more attention to river shipments to the South, but is short of barges and boats to handle it. It is reported that some high-grade West Virginia coal has been moving into the Cincinnati market, and selling at prices under some of the eastern Kentucky coals during the week, this showing how hard set the big companies are for business.

Cancellations have been coming rapidly, and many operators have received numerous hold orders. However, on most of these hold orders, if not claused in the contracts, operators are going right ahead and shipping, and if necessary expect to go into the courts to hold the contract makers, who are using numerous methods of getting out. One of the chief methods is to declare the coal to be of a grade under that purchased, and due to the fact that fast mining methods have reduced quality, it will in many cases be a hard matter for the operator to prove that the coal isn't under grade.

BIRMINGHAM

Inquiry for steam coal much improved, and buyers active. Domestic demand still strong. Receipts of both grades inadequate to meet requirements. Influenza again prevalent and badly crippling production.

Improvement in the demand for steam coal in this market has been very marked during the past week, and consumers have been active in an effort to purchase the needed fuel. Furnace companies, oil mills and other large users have been buying up all the free coal available, while the railroads have been endeavoring to accumulate some surplus for the approaching holidays, some lines being short on current requirements. The activity in the trade is attributable to some extent to the desire to stock coal to tide over the idle period around Christmas, but brokers and sales managers are of the opinion that there will be a satisfactory demand for coal at least through the winter months. At present there is no accumulation of coal in this district and it appears that normal production will not be reached again in the near future.

Domestic consumers are buying freely—that is, as freely as the receipts will permit. Much more coal is needed by dealers than they are able to obtain. The stocks on hand are very small and any number of yards depend entirely on shipments received periodically, the coal being sent out direct from the car to the customer.

Coke

CONNELLSVILLE

Coke production increasing slowly. Furnaces less insistent for deliveries. Discussion of contracts for next year. Inspection system established. Less screening of old dumps. Market still firm.

Coke production in the Connellsville region is increasing slowly. Since the termination of the war men have shown less disposition to work and operators are not urging them. Influenza is on the wane, but men are expected to be fully recovered before they resume work. The shortage of coke has resulted in a few furnaces being banked in the past three weeks and others slowing down, but the blast furnaces are making no very strenuous efforts to secure full supplies of coke and operators are probably taking their cue that market prospects will be helped by curtailed operations.

There is practically a deadlock between coke producers and the furnacemen as to contracts for 1919. Some contracts were put through before the end of the war, the terms of which are not definitely known. Sellers claim that the contracts provide that in case of discontinuance of Government prices the last Government price shall rule, while buyers claim the contracts call for settlement, in that event, at open market prices ruling. Each party endeavors to give the impression that the bulk of the contracting has been done, on the terms he mentions, obviously with the idea of inducing the making of other contracts on those terms.

Furnacemen who have been much annoyed at the quality of coke they have been receiving during the war have caused the institution of a new system whereby there will be inspectors at ovens, representing the buyer, who will pass upon all coke before it is shipped. The furnaces are anxious for improved quality first and a lower market next, but are not particularly anxious to see a lower market at once, as that would have an unfavorable sentimental influence upon pig iron prices, which the furnaces wish to maintain as long as possible after Government control formally disappears Dec. 31. There are no market offerings to speak of, except limited quantities of foundry coke, and the market is quotable steady at the Government limits; Furnace, $6; foundry, 72-hour selected, $7; crushed, over 3-in., $7.30, per net ton at ovens. Demand for screenings from old dumps, which were limited to $5.50 for sizes over ¾-in., has become very small, and some cut prices have been made, but contractors generally are disposed to quiet the business rather than make any large concession.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Nov. 30 at 256,715 tons, an increase of 14,610 tons, and raw coal shipments at 192,038 tons, an increase of 26,242 tons.

Buffalo—Scarcity of men in the coke districts has stiffened the market for high grades, so that the furnaces are finding it hard to get what they need. Buffalo furnaces that depend on byproduct coke have had to go into the open market for a great part of their stock. The supply ought to increase soon, but at present the demand for foundry and furnace grades is such that the prices would double but for the Government restriction. Fuel coke is easy where it has to compete with bituminous, but very strong if it has to do with anthracite substitution. Iron ore by lake is about all in for the season, the amount received for the week being only 99,688 tons.

Middle Western

GENERAL REVIEW

News that Fuel Administration is to relinquish all control of soft coal causes consternation. Little change booked for in market conditions before Jan. 1.

The latest information from Washington indicates that there has been an increase of 12 per cent. over the tonnage produced for the week previous. This, in a way, is hard to understand, because operators and sales agents both are having great difficulty in moving the coal produced for the present market, which is very weak.

Mr. Garfield's interview with the press on Saturday afternoon, in which interview he stated that he had under advisement a plan for abolishing all zones and restrictions on bituminous coal, as well as all price regulations, has caused a furore in the Mid-West market. If Mr. Garfield should take the steps which he is considering, it would lead to the greatest confusion and disorganization throughout this whole district.

The first thing to happen would be that operators with mines in West Virginia and southeastern Kentucky, would immediately get a lot of Chicago business, as there has always been a considerable tonnage of Eastern coal used in this city, but as soon as the war began, these firms were forced to use Illinois and Indiana products. If Eastern coal comes into the market, it will, of course, drive out coal produced in our own territory, and will tend to depress the market still further.

Rumors continue to come into Chicago to the effect that large storage piles, scattered throughout Michigan, Illinois, Indiana, Wisconsin and Iowa, are being consumed with reasonable rapidity, and that two or three weeks' cold weather will mark a great reduction in these storage piles. This, of course, is encouraging, because as soon as the average factory has used up some of its surplus, it will once more come into the market for further purchases.

CHICAGO

Steam coal market is weak and domestic demand is nil. Not much change in anthracite. Plenty of hard coal in dealers' bins, but red tape holds up deliveries.

The steam coal market in this city is weak, and conditions do not differ to any material extent from the general situation throughout the Middle West. Coal is to be had at a decided discount, and, as has been the case right through the season, the only coals that have been strong at Government price current at time of shipment are the high-grade fuels from the Indiana fourth vein district and parts of the southern Illinois field.

The domestic trade continues to be stagnant; this in spite of the fact that we have had, within the last week or so, some reasonably cold weather. It is a common sight, on a cold morning, to see regular processions of coal wagons leaving the retailers' yards, and it is a curious thing to note that the retailer has not come in the market to buy coal to replace the coal sold The reason is perhaps that he is waiting to see whether the zones will really be lifted, in order that, if this proves to be the case, he will be in a position to fill his bins with high-grade Eastern fuels.

The anthracite situation is not much changed. The dealers apparently have plenty of anthracite in their bins, but are prohibited from delivering it by a mass of rules and regulations promulgated by the State Fuel Administration.

MILWAUKEE

Coal market unusually tranquil for the season. Shortage of anthracite the main feature. Stocks of bituminous heavier than last year.

An announcement by State Fuel Administrator Fitzgerald that the amount of anthracite needed to make up the allotment of Wisconsin and other Northwestern states is ready for shipment, has served to encourage dealers who have not as yet been able to get the 80 per cent. of their normal supply allowed by the fuel administration. Those who have received their share have been shut off from anthracite supplies since Dec. 1. However, there are only a few days of lake navigation left, and it may be that cold weather will halt the coal on its way up the lakes. It is understood that five vessels, whose capacity aggregates about 40,000 tons, have been chartered to bring this late supply of coal to market, at a freight rate of $1 per ton. Should Lake Superior become closed the coal will be brought to Lake Michigan ports and sent out by rail. Plans for stimulating distribution in this way have been perfected.

The November movement of bituminous coal was the lightest of any month since navigation opened in spring. The receipts aggregate 251,754 tons. Hard coal receipts were more satisfactory, the record being 115,879 tons, or the largest since August, when 119,293 tons were received. With December to hear from, cargo receipts of anthracite sum up 675,843 tons and of bituminous 3,402,883 tons.

The docks are loaded with bituminous coal, with a quiet market for the same. The hue and cry about coal shortage induced many consumers to stock up with rail coal from Illinois and elsewhere, and this measure of preparedness is reflected in the market conditions of the present. Consumers have been supplied with anthracite in a partial way, but unless there is a reasonably substantial increase in receipts before navigation closes, many will be forced to purchase higher-rail coal.

ST. LOUIS

St. Louis presents the worst demoralized coal market that has been experienced in three years. There is a surplus of all coal, with no market at all to absorb it, either steam or domestic. Plenty of equipment, transportation good and prices cut.

The condition of the St. Louis coal market is worse than it has been at any other time in the past three years, everything considered. The weather continues unusually mild and more so perhaps than it has been in any other season for several years. The dealers in St. Louis have about 80,000 tons of coal in storage. The Polar Wave Ice and Fuel Co. has 30,000 tons, and Schroeter Brothers have 15,000 tons. The balance is scattered. In addition to that it is estimated that there is about an additional 100,000 to 150,000 tons in storage by manufacturing plants. Efforts to use up this storage coal have almost entirely shut off mine shipments.

Retail dealers have begun cutting their retail prices. One dealer had his prices cut for a couple of weeks, but another retailer, a subsidiary of the Taylor Coal Co., of Chicago, began cutting the Carterville coal 50c. a ton. The result is that the entire trade cut the price anywhere from 50c. to 75c. a ton, and even at that no coal is moving. A general wave of dissatisfaction has taken possession of the public, and there is considerable criticism because they were induced to put their coal in early at a high price and now there is plenty of coal at a much lower price.

The Standard field is almost shut off on commercial shipments. A good tonnage of railroad coal continues to move out, but this is not what it should be, though it is the only thing that is keeping the mines in the Standard district working. Some mines have had the same coal unbilled now for two weeks. This coal is selling in the St. Louis market at from $1.75 for 2-in. lump up to $2 for 6-in., with nut and egg at about the same price and screenings at from $1.35 to $1.50, with mine-run at $1.65 to $1.70. The operators in this district contend that it costs them between $1.50 and $1.75 to produce coal, so it is a case of where they are down to selling coal at the cost of production or less.

The Mt. Olive field presents a somewhat better condition, although that coal has to some extent been cut to $2.40 and some coal with the Mt. Olive classification in St. Louis is selling as low as $2.25 for the screened domestic sizes. A fairly good railroad tonnage from this field continues to move out and in addition there is a fair demand from the north for coal of this quality, but the mines here are idle on account of no orders and there is considerable unbilled coal.

In the Carterville district of Williamson and Franklin County, as well as in the Duquoin field, there is a surplus of coal at practically all mines, and were it not for the railroad business in these districts the mines would have to shut down on account of no orders. As it is, some mines have unbilled coal right along. Car supply is good and transportation shows a setback the past week or so.

The coals from these fields are holding up fairly well, but they can be purchased as low as $2.40 for the screened sizes, and screenings are a little weak. Very little demand for mine run.

It is a weather proposition from now on. Unless seasonable weather comes a further demoralization of the entire southern Illinois coal business is a certainty.

SEATTLE

Fuel restrictions to be practiced during the winter owing to falling off in production. Thorough investigation made of state coals.

Fuel restrictions will be continued this winter notwithstanding the signing of the peace armistice, according to the state fuel administrator, who states that a falling off in production has made the restrictions necessary and a need to continue the fuel administration office.

The Federal Fuel Administrator for the state, W. W. Miller, is now holding conferences with committees he appointed earlier in the year relative to a series of experiments with Washington coal to find the widest possible use of all grades, and to provide for their utilization in the best way to obtain the greatest saving in consumption and cost. Studies have been made at the mines and in the laboratories, and an interesting report is in the course of preparation by the fuel administration.

During the epidemic of influenza it is now estimated that the output of coal mines in the state fell 60 per cent. for a period of a little more than three weeks, and even yet the mines are not producing what they did previous to the visitation of the sickness.

CURRENT PRICES—MATERIALS & SUPPLIES

No. 2 grade	1.30	1.55	1.65	1.90	2.00	2.25

Asbestos asphalt saturated felt (14 lb. per square) costs $5.35 per 100 lb.

Slate-surfaced roofing (red and green) in rolls of 108 sq.ft. costs per $2.40 roll in carload lots and $2.65 for smaller quantities.

Shingles, red and green slate finish cost $5.75 per square in carloads, $6.75 in smaller quantities, in Philadelphia.

ROOFING MATERIALS—Prices per ton f.o.b. New York or Chicago:

	Carload Lots	Less than Carload Lots
Tarfelt (14 lb. per square of 100 sq.ft.)	$64.00	$65.00
Tar pitch (in 400-lb. bbl.)	21.00	22.00
Asphalt pitch (in barrels)	40.00	45.50
Asphalt felt	72.50	77.00

HOLLOW TILE—Price per block in carload lots for hollow building tile:

	4x12x12	8x12x12	12x12x12
St. Paul	$0.056	$0.11	$0.162

MISCELLANEOUS

GREASES—Prices are as follows in the following cities in cents per pound for barrel lots

	Cincinnati	St. Louis	Birmingham	Denver
Cup	7.2—8.2	6.9	8½	14½
Fiber or sponge	7.2—8.2	13	8½	18
Transmission	7.2—8.2	13	0	20
Axle	4.6—4.9	3.9	3¾	5¼
Gear	4.9—7.1	9.5	8	9
Car journal	4.9	4.5	5	8

BABBITT METAL—Warehouse prices in cents per pound:

	New York		Cleveland		Chicago	
	Current	One Year Ago	Current	One Year Ago	Current	One Year Ago
Best grade	95.00	70.00	83.00	80.00	96.00	70.00
Commercial	45.00	40.00	23.00	21.00	25.00	25.00

HOSE—Following are prices of various classes of hose:

	Fire
	50-Ft. Lengths
Underwriters' 2½-in.	85c. per ft.
Common, 2½-in.	25%

	Air		
	First Grade	Second Grade	Third Grade
¼-in. per ft.	$0.65	$0.40	$0.30

Steam—Discounts from list
First grade.....15% Second grade.....25% Third grade.....33⅓%

LEATHER BELTING—Present discounts from list in cities named:

	Medium Grade	Heavy Grade
St. Louis	30–50%	35%
Denver	35–5%	40%
Birmingham	35%	40%
Chicago	45%	35%
Cincinnati	40–10%	30%

RAWHIDE LACING—25% off list.

PACKING—Prices per pound:

Rubber and duck for low-pressure steam	$0.99
Asbestos for high-pressure steam	1.76
Duck and rubber for piston packing	1.10
Flax, regular	.99
Flax, waterproofed	1.21
Compressed asbestos sheet	1.10
Wire insertion asbestos sheet	1.30
Rubber sheet	.66
Rubber sheet, wire insertion	.99
Rubber sheet, duck insertion	.55
Rubber sheet, cloth insertion	.25
Asbestos packing, twisted or braided, and graphited, for valve stems and stuffing boxes	1.21
Asbestos wick, ½- and 1-lb. balls	.75

MANILA ROPE—For rope smaller than ⅝-in. the price is ½ to 2c. extra; while for quantities amounting to less than 600 ft. there is an extra charge of 1c. The number of feet per pound for the various sizes is as follows: ⅛-in., 8 ft.; ¼-in., 6; ⅜-in., 4½; ½ in., 3½; ⅝-in., 2 ft. 10 in.; ¾-in., 2 ft. 4 in. Following is price per pound for ⅝-in. and larger, in 1200-ft. coils:

Boston	$0.34	Birmingham	$0.39
New York	.36	Denver	.36
Cincinnati	.33½	Kansas City	.34½
Chicago	.33	Seattle	.33
St. Paul	.34	St. Louis	.33½
San Francisco	.32	Los Angeles	.34

PIPE AND BOILER COVERING—Below are discounts and part of standard lists:

PIPE COVERING		BLOCKS AND SHEETS	
Pipe Size	Standard List Per Lin. Ft.	Thickness	Price per Sq.Ft.
1-in.	$0.27	½-in.	$0.27
2-in.	.36	1 -in.	.30
6-in.	.80	1½-in.	.45
4-in.	.60	2 -in.	.60

FREIGHT RATES—On finished steel products in the Pittsburgh district including plates, structural shapes, merchant steel, bars, pipe fittings, plain and galvanized wire nails, rivets, spikes, bolts, flat sheets (except planished), chains, etc., the following freight rates per 100 lb. are effective:

Boston	$0.30	New Orleans	$0.38½
Buffalo	.17	New York	.27
Chicago	.27	Philadelphia	.24½
Cincinnati	.23	St. Louis	.24
Cleveland	.17	St. Paul	.49½
Denver	.99	Pacific Coast (all rail)	1.25*
Kansas City	.59		

Note—Add 3% transportation tax. * Minimum carload, 80,000 lb.

COAL AGE

Volume 14 New York, December 19, 1918 Number 25

[Members of fighting regiments from the United States who came from the anthracite coal regions were overjoyed at the news that they were shortly to be returned to private life and their former occupations.—NEWS ITEM.]

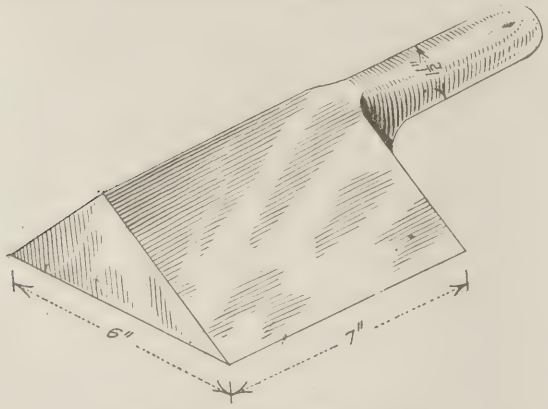
Back to the Mines!

Written expressly for COAL AGE

BY RUFUS T. STROHM

The fightin's done an' the last big shell's
  Gone screamin' acrost the hill,
An' but for the doughboy's joyful yells
  The world 'ud be mighty still;
The boche is groggy, believe me, bo,
  An' he's tickled to quit, be gee!
There's nothin' doin' out here, an' so
  It's back to the mines for me!

I've dug my last six feet of trench
  An' I've throwed away my spade,
An' I give my shoulder an orful wrench
  When I heaved my last grenade.
I kin can this twaddle of "parley-voo"
  An' cut out the fool "wee, wee,"
For now that there ain't no job to do
  It's back to the mines for me!



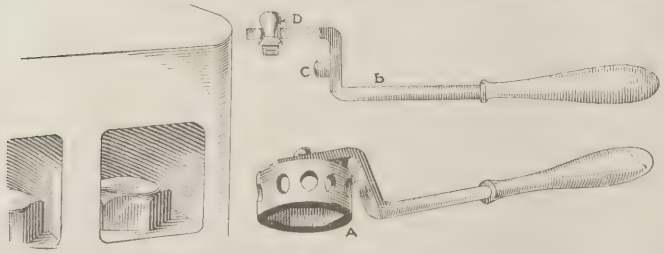
No more I'll stan' on the firin' step
  A-waitin' to draw a sight
On some poor Fritzie that ain't got hep
  To the way us Yankees fight;
An' my score'll stop where it is just now,
  At a measly twenty-three;
The sport's called off, an' I reckon how
  It's back to the mines for me!

There ain't no sense in my loafin' round
  Eatin' three square meals a day,
When there's tons of coal hidin' underground
  An' the winter's on the way;
So I kinda think that I'll hit the trail
  For the lan' of the brave an' free,
An' grab my pick an' my ol' tin pail—
  It's back to the mines for me!

IDEAS AND SUGGESTIONS

Simple Car Chock

A type of car chock not mentioned in the article on chocks in *Coal Age* of Nov. 28, p. 973, is shown in the accompanying illustration. This chock, which is used mostly at shaft bottoms and similar places, is triangular in cross-section, 5 to 6 in. wide and about 2½ in. thick. One end is formed into a handhold, or handle. This



EASILY MADE CAR CHOCK

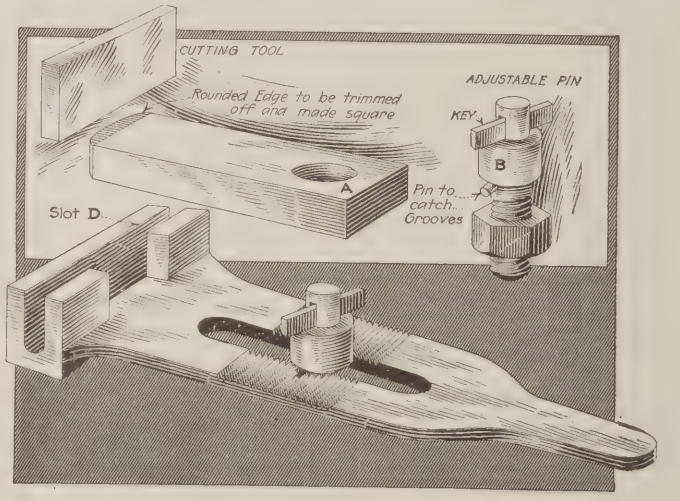
chock may be shaped easily with an ax and serves its purpose admirably. In use it is ordinarily placed in front of the second wheel of the car, as in this position it has less tendency to push the car sidewise or off the track. It may be easily knocked from its place either by the foot, by a sharp blow from another chock or from a heavy stick.

Ratchet Wrench for Close Quarters

By A. J. Lucas
Ozone Park, N. Y.

The repairman in and about the mine is often confronted with the task of loosening or taking up nuts located in such narrow openings as shown in the accompanying illustration; it is almost inaccessible with a wrench of any ordinary type. To overcome this dif-

DETAILS OF A RATCHET WRENCH



ficulty I made the ratchet wrench shown to the right in the illustration. The hexagon part *A* of the wrench is made by forging a piece of suitable steel pipe around the nut and drilling holes on its circumference. The handle *B* is provided with a pin *C*, which fits the holes in the wrench body. It is fastened to the upper part of the wrench by means of the formed pin *D*. The operation of this wrench is self-explanatory.

Squaring Crusher Hammer Ends

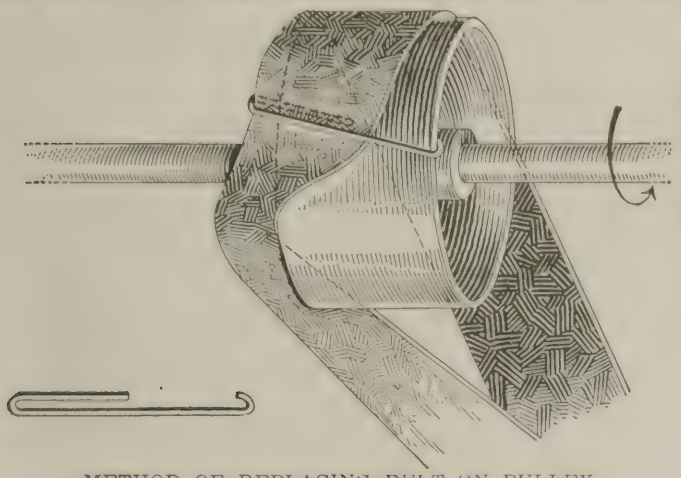
By J. W. Bailey
St. Louis, Mo.

L. W. Tabor, machine shop foreman at the coke plant of the Laclede Gas Light Co., of St. Louis, reports that he was confronted with a troublesome proposition in the shape of keeping the steel hammers of the coal crushers sharp and square edged. He solved his difficulty in the manner here described.

These hammers when new are about 14 in. long, 6 in. wide and 1 in. in thickness, and number considerably over 100 to a set. Use wears the ends round and of little service, making it necessary to trim the worn ends quite often. One set trimmed in the ordinary way by the shop blacksmith required several days' time, considerable coke and an additional blacksmith to attend to the regular requirements of the shop.

DEVICE USED TO KEEP HAMMERS IN CONDITION

To eliminate the excessive use of coke and conserve on fuel in heating the hammers, Mr. Tabor devised a gas furnace that would heat just enough of the ends to be practical and accommodate six hammers at one time.



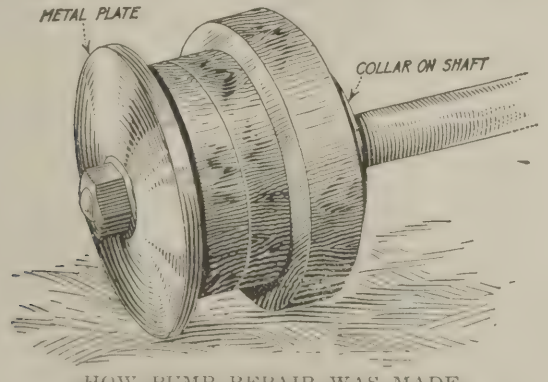
Then he constructed the device shown in the accompanying illustration, which facilitated the work and enabled the blacksmith to finish an entire set in a few hours. This in turn eliminated the hire of an extra man in times when men are scarce.

This jig measures about 36 in. over all. The pin *B* is set on a grooved surface so as to gage the proper length. The hammer when heated is placed with the hole *A* over the pin *B*. The key is then placed in the pin *B* to hold the hammer firm. The cutting tool is then set in the slot *D* over the rounded and heated portion of the hammer, and a steam hammer is brought to bear on the cutting tool, finishing the operation. This device insures a perfect edge on all hammers as well as uniform lengths. About a quarter of an inch is taken off at each trimming.

Putting on Heavy Belts

The accompanying illustration shows a simple device for putting on heavy belts when it is necessary to shut down in order to do so, and where a rope is usually employed for the purpose.

Take a piece of a $\frac{5}{16}$ or $\frac{3}{8}$ in. round iron and bend it as shown in the small sketch. Hook the short end over



METHOD OF REPLACING BELT ON PULLEY

the edge of the rim of the pulley and the long end under the belt, as indicated. Start the engine slowly, and when the belt is on it is not necessary to stop, as is the case when a rope is used, because the short end of the hook will always straighten out and disengage itself. It is a good plan to use a bar of as light iron as will answer the purpose, since it will straighten out and free itself with less stress on the belt.

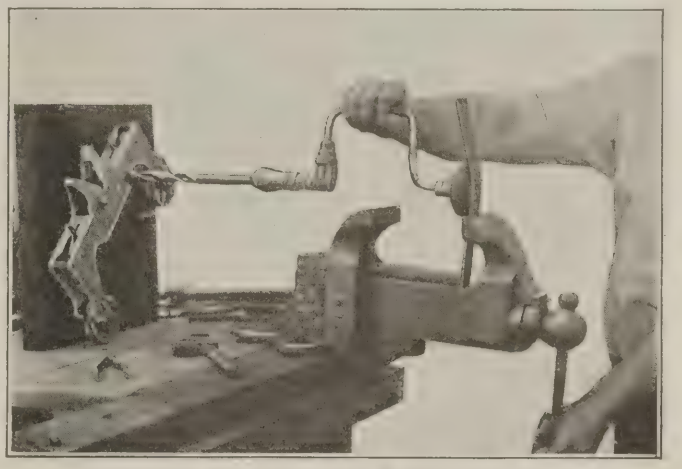
Emergency Pump Repair

By S. D. Hainley
Osceola Mills, Penn.

One Saturday morning, on going to an electrically driven pump that handled the water from an important section of the mine, I found that the machine was not working properly. The water at this time was already above the rails, so that the section could not be operated that day. Taking the pump apart, it was found that the metal portion of the piston had been practically

HOW PUMP REPAIR WAS MADE

eaten up by the acid of the water. A new piston and a piston rod were at once ordered. These were promised to arrive on the following Monday morning.



Monday morning came, but no piston arrived. Tuesday and Wednesday rolled around, and still no piston. All this time the water was rising. Something had to be done, or at least attempted. Accordingly I got a piece of 2-in. oak plank and sawed out a circular section $\frac{1}{4}$ in. less in diameter than the bore of the pump cylinder. The edge of this was then cut away to a depth sufficient to take $\frac{3}{8}$-in. packing and for a length of 1 in. A piece of 1-in. oak board was now procured, sawed to this same diameter and attached to the piece of 2-in. plank.

As the available length on the piston stem or rod was not sufficient to accommodate another 1-in. piece, a metal plate was used. This was made slightly smaller than the bore of the pump and was held in place by the regular piston nut.

When this improvised piston was fitted with packing and put in place it gave as good satisfaction as had the regular piston. In fact, this device gave excellent service until the acid ate up the iron plate and permitted the packing to come off. When I asked the superintendent to have another plate made he immediately suggested that I make a wooden one!

Drilling with the Vise

The rig shown in the accompanying illustration will often solve difficult problems, such as drilling large holes in metal, when a drilling machine is not available. Such circumstances often arise in connection with the work

METHOD OF DRILLING WITH THE VISE

of the repairman. A ratchet brace is used for the movement of the drill, while the feed is obtained by means of the vise, which is equipped in the manner shown. An angle-plate or any suitable object can be employed for the proper location and backing for the piece to be drilled.

The relatives and friends of men imprisoned in a mine in case of an explosion or other accident are most vitally concerned in the recovery work and the public in general is much interested in the probable loss of life and the efforts made for promptly exploring the mine in order to rescue the living and to recover the dead. A local official of the mine should be designated by the manager or the superintendent to take charge of an information bureau in a building somewhat removed from the mine entrance. This official from time to time should give out, for the benefit of the entombed men's families and the public, definite information concerning the progress of the rescue and recovery work.—*Rescue and Recovery Operations in Mines.*

Plant of the Williams Pocahontas Coal Co.

By GEORGE S. JAXON
Philadelphia, Penn.

FIG. 1. GENERAL OUTSIDE VIEW OF THE WILLIAMS POCAHONTAS COAL CO.'S PLANT

THE present-day demands that the entire output of a coal mine be properly cleaned and sized in order to conform to the exacting requirements of its customers brings to the attention of the industry certain sizing plants which are worthy of mention. One of these is the modern wood-construction coal tipple of the Williams Pocahontas Coal Co., at War, McDowell County, West Virginia, on the Dry Fork branch of the Norfolk & Western R. R. The operation is known as the Howard mine and is comparatively young, having started shipping coal in May, 1916. The workings are in the "War Creek seam," which varies in thickness from 66 to 72 inches. A general outside view of the plant is shown in Fig. 1.

At the commencement of mining operations, coal from the working face was brought out in mine cars constructed of wood. From these it was dumped into an inclined wood storage chute, built on practically the same slope as that of the mountain profile. At the lower end of this chute gates were installed for drawing out quantities of coal and depositing them in a mine car which was drawn back and forth over a wooden trestle by a mule, and delivered to a dump hopper over the railroad car, which was located at approximately 160 ft. from the discharge gates of the storage hopper.

This crude method of loading straight run-of-mine coal, as shown in Fig. 2, in no way satisfied the officers of the coal company. The result was that around Christmas, 1916, designs for a new modern equipment were being considered. In March, 1917, Frank W. Truscott, the president of the company, signed a contract for a sizing and cleaning plant of such proportions as to properly handle a capacity of 150 tons of run-of-mine coal per hour, and prepare it in four different sizes, the three larger of which would be hand-picked. The different grades were based upon the following percentages: Lump, 25 per cent.; egg, 18 per cent.; nut, 17 per cent.; slack, 40 per cent. Total, 100 per cent.

The system of mining followed at this operation is that known as the "wall-and-pillar." Electrical mining machines are employed. The following is an illustrated description of the equipment that was chosen as the one being the most suitable to fulfill the requirements.

A trip of mine cars which are of about two tons capacity each are hauled by electric motor and spotted adjacent to the scalehouse. The cars are then cut loose from the motor and one at a time delivered to a Phillips crossover dump, after each car has been properly weighed on a platform scale. The dump empties each car as received into a substantial wood-frame hopper of about five tons capacity. This is lined with $\frac{3}{16}$-in. steel plates, the lining being held in place by means of countersunk bolts.

Attached to the bottom of this hopper is a reciprocating plate feeder which delivers the coal in a measured quantity to the trough of the lower strand of a re-

tarding conveyor. The crank of this feeder is so designed that the stroke may be easily and quickly changed to suit the capacity requirements. This feeder receives its mechanical power through spur gearing and chain drives from the take-up shaft of the conveyor.

The retarding conveyor here employed without question has been carefully designed and built for heavy service. Its speed of travel is 80 ft. per minute and it has an entire length of 255 ft. from center of head sprocket to center of tail sprocket. Of this length, 105 ft. is on an incline of 20 deg., while the remainder at the discharge end is horizontal. The inclined and horizontal sections are connected with a 75-ft. radius curve. This machine is employed for transporting the coal from the feeder to the shaking screens. The flights are made of ¼-in. steel plates and measure 10 in. deep by 30 in. long. They are rigidly attached at intervals of 36 in. to a double strand of 18 in. pitch-steel strap-bushed roller chain. The side bars of this chain are constructed of 2½ x ⅜-in. flats, the joints being ¾-in. riveted steel pins provided with bushings and encircled with 3¼-in. straight-face solid cast-iron rollers, which travel on both the carrying and return runs along steel bar trackage secured to the wooden frame by means of countersunk bolts.

At the lower end of the conveyor a large rack-and-pinion discharge gate is introduced for the purpose of permitting the discharge of run-of-mine coal direct to a 36-in. picking table 20 ft. long from center to center of sprockets. The coal is cleaned on this table prior to delivery to the railroad cars, but this

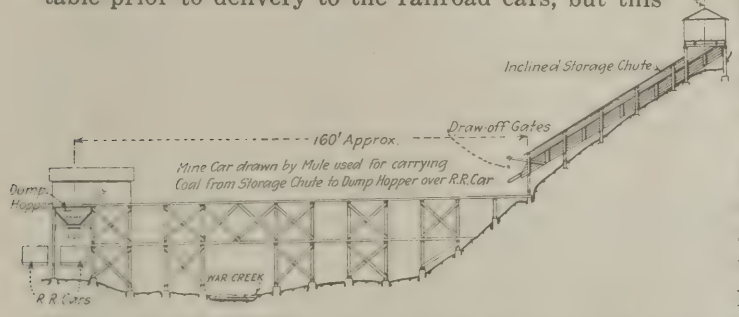


FIG. 2. CRUDE METHOD OF LOADING RUN-OF-MINE COAL

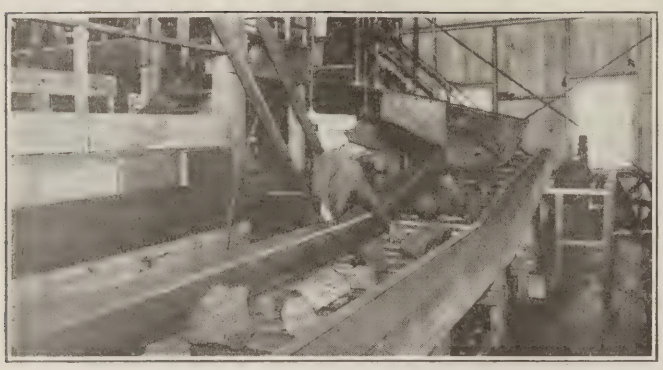
part of the equipment is only used in case of emergency when, for some reason, portions of the tipple equipment may be out of commission.

Fig. 3 shows the emergency run-of-mine table and the pickers at work. This table is constructed of $\frac{3}{16}$-in. steel pans of 9-in. pitch attached to a double strand of roller chain which travels at a speed of 50 ft. per minute. The extreme lower end of the retarding conveyor is the

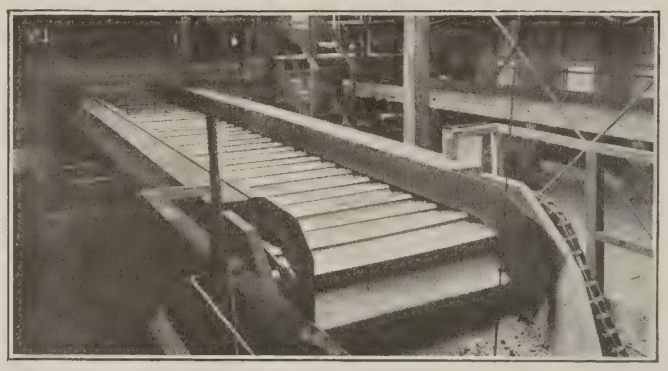
FIG. 3. VIEW OF PICKERS AT WORK ON EMERGENCY RUN-OF-MINE TABLE

FIG. 4. VIEW OF THE SHAKER SCREENS

regular discharge point, where the coal is delivered without drop onto a steel chute which in turn delivers it to the sizing shaking screens.



The screening unit is composed of an upper and a lower screen, both being of the hanger-rod type. Each screen has a width of 60 in. and a length of approximately 25 ft. Each is moved back and forth at a speed of 100 shakes per minute.



The upper screen is utilized for separating slack and nut coal from the lump and egg, this separation being accomplished by means of slotted lip screen plates. This screen is so designed that the slack is delivered to the slack hopper directly below, while the nut coal may be delivered to the nut coal picking table, or by means of a fly valve in the lower deck of the screen it may be delivered and mixed with the slack in the hopper mentioned above.

The lower screen is equipped with the same type of slotted lip screen plates as mentioned above and also bar screens, and is used for removing or separating the egg size from the lump. The slotted lip screen plate is used when preparing 4-in. egg, and the bar screen when preparing 8-in. egg, the latter size being known as 8-in. run-of-mine. A veil plate is used for covering the 8-in. bar screen when this size of product is not being prepared.

These screens are shown in Fig. 4 and are operated by means of an eccentric shaft of ample proportions to oscillate them easily at the speed mentioned. They are connected to this shaft by ball-and-socket eccentric rods, which insure perfect alignment in operation. A successful shaking screen unit depends largely upon being carefully balanced. In the designing of these screens considerable study was given to attain this end.

The cleaning operation of the three sizes of coal—lump, egg and nut—is carried on in the following manner: Each size is automatically discharged onto a slow-moving overlapping corrugated apron picking table. The lump table shown in Fig. 5 is 36 in. wide and 66 ft. long, but has 30 ft. of its length mounted within a structural steel boom, for the purpose of delivering the lump coal without breakage to the railroad cars. The apron is constructed of a continuous section of $\frac{3}{16}$-in. steel pans, or flights, mounted on a double strand of 9 in. pitch steel roller chain with ¾-in. steel riveted pins at the joints. Rollers of 3¼ in. diameter encircle a case-hardened steel bushing, which in turn encircles the

FIGS. 5 AND 6. VIEWS OF LUMP, EGG AND NUT PICKING TABLES

joint pins. This table travels on flat steel bar track mounted on wooden framework along the horizontal picking section.

The egg and nut tables, as shown in Fig. 6, are similar to each other and are 48 in. wide and 32 ft. long each from center of head sprockets to center of foot sprockets. Both of these tables are horizontal and are constructed of the same kind of chain as that employed in the lump table, the only difference being that the steel corrugated flights have greater width to accommodate the smaller sizes of coal, which demand a thinner layer on the table for picking purposes.

These tables have no loading booms attached directly to them, but at the head end a discharge chute is introduced for the purpose of receiving the coal and delivering it to a special Link-Belt loading boom chute. The discharge chutes are provided with flygates made of perforated metal, the intention of these being to rescreen the coal as it is discharged from the picking table and so take out the fines which have been unavoidably made by the pickers on the table. These are deposited in the cross mixing conveyor, which is located directly below. By lifting the perforated-metal hinged flygates in these chutes all coal passing over the picking tables may be delivered to the cross conveyor for mixing purposes, or to the domestic coal bin as the case may demand.

Fig. 7 shows all three loading booms quite clearly. The lump boom being part of the lump table, as before mentioned, needs no explanation. It will be noticed that the booms which are utilized for egg and nut are of a distinct and separate type from those usually seen and are an entirely new feature in loading-boom design. These booms have proved themselves successful and have been used to good advantage in several other operations. They are of the drag scraper type and are constructed of a single strand of malleable iron H class chain, the carrying or top strand of which travels on the inside of a $\frac{3}{16}$-in. steel trough, with flared sides to prevent the crowding of coal en route, the chain and trough being supported on main channel members.

These units are each 27 ft. centers of head and foot

FIG. 7. INTERIOR VIEW OF TIPPLE, SHOWING THE THREE LOADING BOOMS IN USE AT PLANT

sprockets and hinged at the upper or foot end, where they receive the coal from the picking-table discharge chutes. The lower, or return, strand runs back on angle guides and is protected along the bottom by means of a plain steel plate which insures no obstructions to encounter the obstacles on the railroad cars, such as brake wheels, etc.

The booms are counterbalanced by means of steel ropes and cast-iron counterweights, while the raising and lowering is performed by means of a simple friction hoist. These hoists are located above the driving ends of the picking tables and are operated by means of a line shaft upon which are mounted paper friction pinions which supply the power for hoisting. By the easy manipulation of a hand lever the operator may either raise or lower the booms at will. This type of friction hoist has given excellent results at several other operations and has undoubtedly been a big step in the direction of simplicity in design of hoisting mechanism for use with loading booms.

The cross mixing conveyor it utilized for several purposes: First, for delivering the fine coal screenings from the picking tables to an auxiliary slack bin located adjacent to the slack railroad track; second, for delivering egg and nut coal to a domestic bin; third, for delivering refuse from the picking tables to the rock bin; fourth, for conveying hand-picked lumps from the egg table to the lump table.

This conveyor is so designed so as to receive in its lower strand from the discharge chutes at the end of the picking tables the following: Egg and nut for the domestic coal bin, the rescreenings from the picking tables and the refuse for the refuse or rock bin, while the upper strand performs the duty of carrying the above-mentioned hand-picked lumps. This machine is constructed of 6-in. pitch, double-strand, steel-strap, link chain with crossbars at 24-in. intervals. The chain travels in a $\frac{3}{16}$-in. steel trough upon a steel bar wearing track, the trough being equipped with a rack and pinion valve over the auxiliary slack bin for the purpose of discharging the fine coal rescreenings from the tables. The valve has three positions: No. 1, wide open to discharge fine screenings; No. 2, a perforated section which takes out fine coal when conveying domestic coal, which insures the delivery of clean egg and nut to the domestic bin; No. 3, a plain blank section which closes up the valve opening and makes a continuous trough when conveying refuse to the rock bin.

The entire plant is operated by means of three-phase, 60-cycle, 440-volt alternating-current motors manufactured by the General Electric Co. These are complete with starting compensators, circuit breakers, no-voltage release and overload relays. One 75-hp. motor is used for driving the reciprocating feeder, retarding conveyor, shaking screens, emergency run-of-mine picking table and cross mixing conveyor, while a 15-hp. motor is employed for driving the lump, egg and nut picking tables, along with the loading booms and friction hoists. All driving gears and parts are properly protected with steel-plate guards and all walkways and stairs are provided with double wooden hand railings.

The tipple building is of longleaf yellow pine construction, properly dressed and thoroughly and substantially braced with steel rods. Considerable thought was given to the lighting and ventilating of this building, the result being that an abundance of windows and skylights are introduced to enable the thorough cleaning of the coal. Fig. 8 shows a general outline drawing of the entire equipment. "Car retarders" are used to facilitate the moving and spotting of railroad cars under the tipple building. Throughout the entire plant it is evident that considerable thought and study have been exercised in even the smallest details, mechanical devices having been properly installed to avoid unnecessary labor in the performance of sizing, cleaning and loading operations. The entire equipment was designed, fabricated and erected complete by the Link-Belt Co., of Philadelphia, Chicago and Indianapolis.

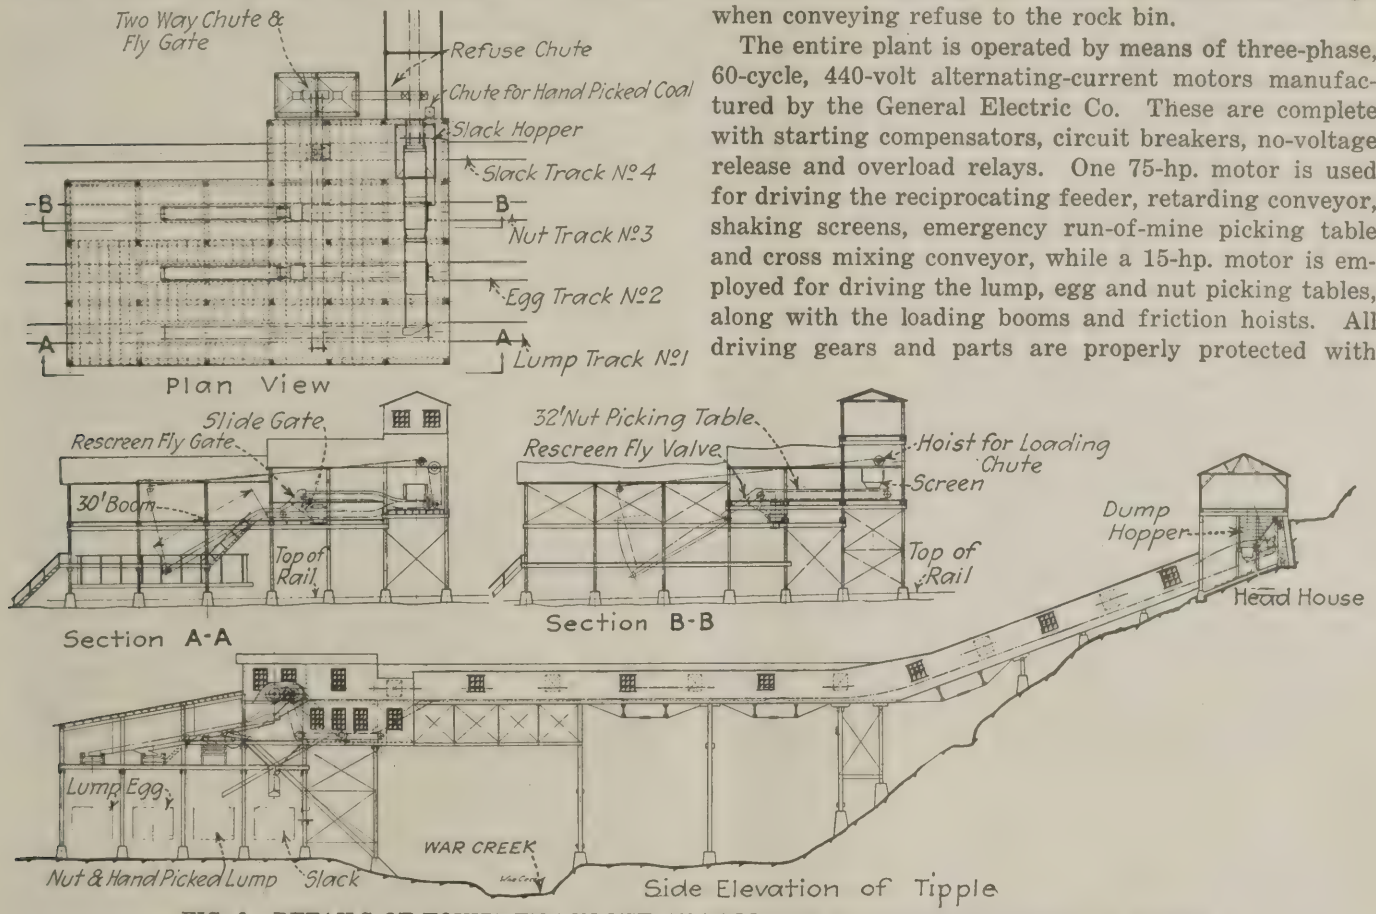


FIG. 8. DETAILS OF EQUIPMENT IN USE AT WILLIAMS POCAHONTAS COAL CO.'S PLANT

Conservation of Explosives*

By S. C. JONES
Greensburg, Penn.

SYNOPSIS — *Much powder and other explosives are destroyed or rendered useless annually through careless or improper storage. The proper placing of the hole in the face and the proper loading and tamping of the charge have much to do with the effectiveness of the shot or the amount of coal brought down per pound of explosive employed.*

ABNORMAL conditions have existed both inside and outside the mines during the time this nation has played such an important part in the world war now drawing to a close. During this period extreme methods have been applied, the prime object in view being to attain maximum production. Slowly but surely a reaction has set in, and changed conditions must inevitably be faced. Explosives being my specialty, I will try to explain briefly some matters that may help to eliminate unnecessary waste and aid in the conservation of explosive materials.

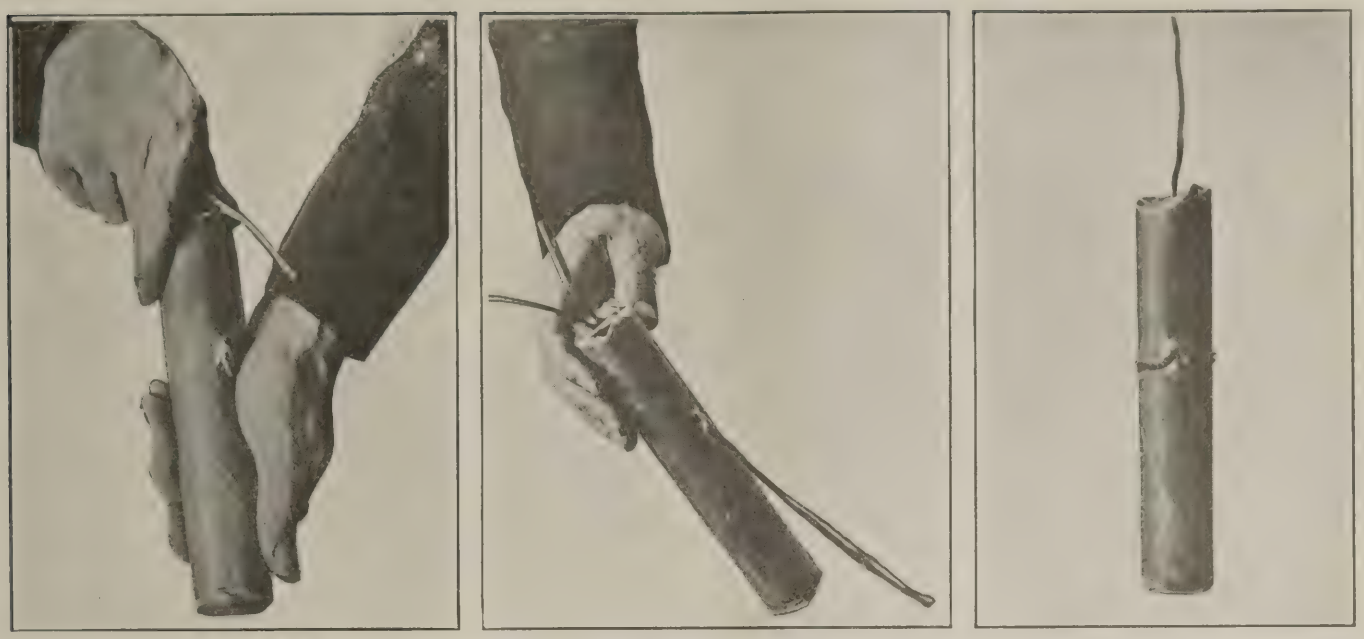
There can be little question that both miners and shotfirers have been, and still are, using excessive amounts of explosives in blasting coal. If this is doubted, let a comparison be made between the present and past cost of explosives per ton of coal mined.

Conditions brought about by the war were responsible for the enactment of the present explosive law in the State of Pennsylvania. This law not only lays down certain regulations, and prescribes who shall handle and dispose of explosives, but it has proved to be the means of conserving and saving explosives, as well as promoting certain safety features.

Under the old regime every little store that wished to do so could handle explosives. Miners bought in any quantity, and of any kind, from 20 per cent. to 60 per cent. dynamite, and from the lowest to the highest grade of permissibles. They took these into the mines without regulation. Tons and tons of these explosives have been wasted because they were stored in mines for long periods and subjected to dampness. Another plan followed in many places was for the men to take their explosives home and store them in some outbuilding or in the cellar. Here again they were exposed to dampness and poor storage conditions.

The law mentioned above has brought about an entire change. It stipulates that all explosives must be stored safely, protected from theft and handled only by responsible persons. It has been my unpleasant duty to destroy tons and tons of explosives rendered unfit for use through bad storage and improper handling. Storage conditions have been and still are bad in many places, and this has caused and still is causing much waste.

Not long ago I visited a plant where the explosives are stored in an underground magazine, the floor of which is 8 ft. below the surface, with no visible means of drainage or ventilation. I also visited another place that was in such a dilapidated condition that one could have shot a cannon ball clear through the building from side to side without touching a timber. I could cite case after case where similar conditions exist. I would suggest that every operator look well into his storage conditions along lines recommended by the manufacturers of explosives, as well as the present law, in order to conserve and save this material.



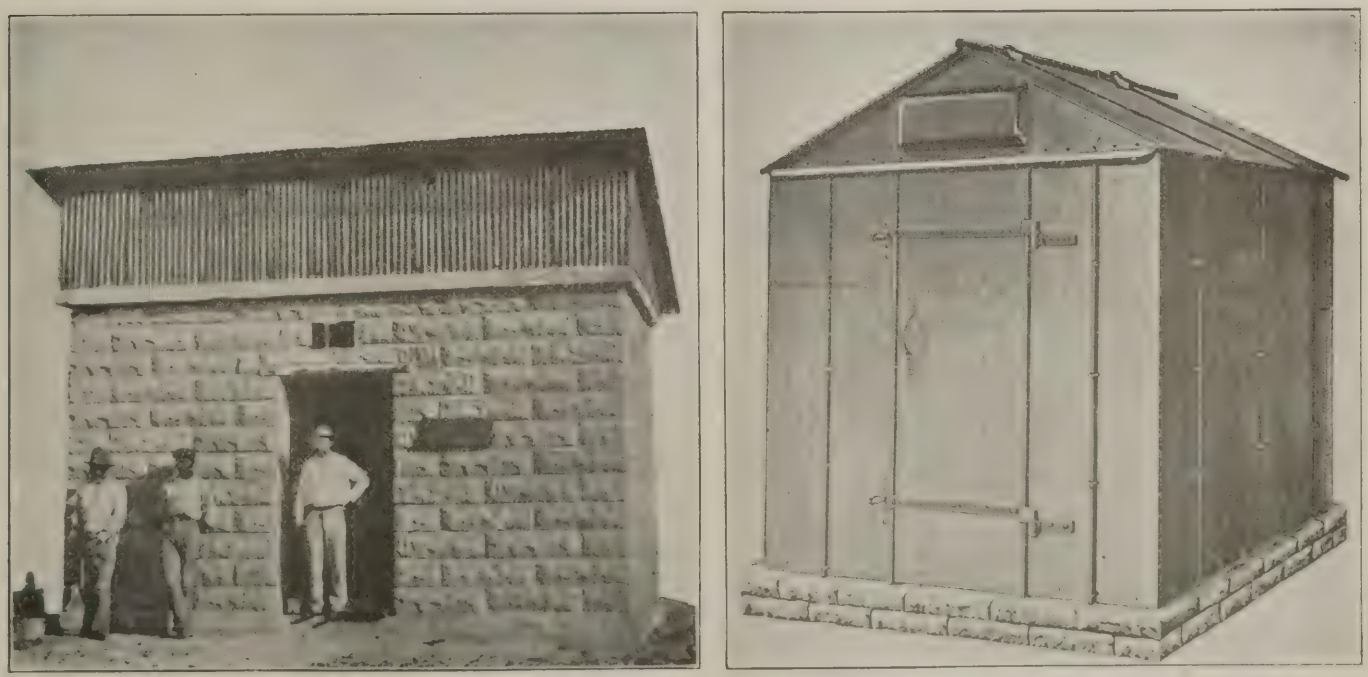
FIGS. 1 AND 2. TYPES OF POWDER MAGAZINES THAT LEAVE MUCH ROOM FOR IMPROVEMENT

Fig. 1 shows a bad storage condition. It will be noticed that there is no chance for drainage, except by digging a long deep ditch, since the floor of the magazine is below the surface of the ground. The surrounding country shows that the magazine is so placed that water or dampness will injure or spoil its contents.

Fig. 2 shows a magazine which is much better, and will meet the necessary requirements of protecting the material stored. Fig. 6 shows an ideal magazine, well built, and with good ventilation and drainage. Fig. 7 shows a portable magazine which will meet all the necessary requirements and protect the explosives contained in it. It can be bought at a small cost, and if kept clean and painted will protect and preserve the explosives in proper condition.

The proper placing of shotholes as to depth and posi-

*Part of discussion on means of conserving mining materials, before the Coal Mining Institute of America, annual meeting, Pittsburgh, Penn., Dec. 5, 1918.

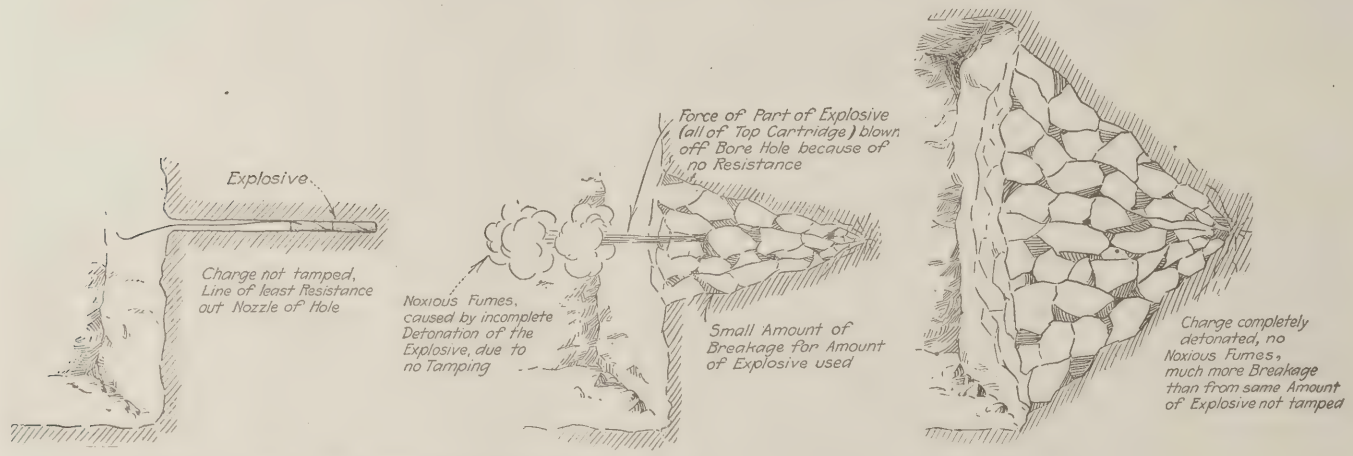


FIGS. 3, 4 AND 5. ILLUSTRATING THE PROPER METHOD OF PRIMING A CARTRIDGE

tion is an important factor, as is also the method of tamping. This fact should be noted carefully: It has been proved beyond a doubt that all explosives, whether dynamite, black powder or permissibles, when property tamped, add from 50 to 70 per cent. to their efficiency. The undercharge, the overcharge, the improper placing of the cap or the electric blasting cap, all are important and worthy of time and consideration in order to save explosives and obtain the highest efficiency from those employed.

Some ten years ago a school was started for the purpose of teaching the proper use of permissibles. I remember one company had 33 traveling instructors engaged in this work. Many readers will recall hearing the question, "How much of your powder do you intend to use for that shot?" The answer, "Three sticks." "Well, 2 to 2½ is sufficient of this powder." In this case the prime motive was not conservation of explosives, but there was nevertheless an evident attempt made at education in the direction of conservation, and to show that a saving was possible.

The proper undercutting of coal is an important matter. If making a 5-ft. undercut, the cut should be an even 5 ft. from rib to rib; if 6 ft., the cut should be an even 6 ft. clear across the room and free from sprags. Careful work means a wonderful saving in explosives.



All fine coal and bugdust should be removed from the undercut. If snubbing is practiced, the coal should be loaded out before second-shooting. The "breaker," or "buster," shot should be fired first. The coal made by this shot should, if possible, be loaded out completely before more shooting is done, as by following this method the best results are attained in the next shot.

FIGS. 6 AND 7. PERMANENT AND PORTABLE MAGAZINES OF GOOD QUALITY

Fig. 7 shows the line of least resistance taken by a shot that is not tamped. To omit the tamping in a shothole in coal is analogous to placing a load of powder in a gun without inserting the wadding or the projectile. Plenty of noise may be made, but little effective work will be done by the charge of powder. Fig. 8 shows the shattering effect on the coal of an improperly tamped shot, while Fig. 9 shows the results of a shot which has been properly tamped.

Figs. 3, 4 and 5 show the proper method of placing the electric blasting cap in the charge of explosives. It will be noticed that a hole is first punched from the center of the end of the stick to the center of the side. A loop of the fuse wire is then pushed through this hole and the blasting cap drawn down into the stick; the lower end of the stick is then passed through the loop and the wire drawn up tight. The proper placing of the detonator in the charge of explosives, the proper placing of the hole in the coal, the proper loading and tamping of the charge, all have a direct bearing on the amount of coal secured per ton of explosive used.

FIGS. 7, 8 AND 9. SHOWING THE EFFECT OF PROPER AND IMPROPER LOADING AND TAMPING

In conclusion, allow me to diverge from the subject in hand and speak of one which is now of great importance; namely, the conservation of man power. During the serious epidemic which has just passed, it was deemed necessary to close the saloons. Many coal-mining men immediately noticed and remarked the general effect on their men and their output.

It has been my privilege to often ask this question of coal mine officials: "What has been the general effect on working conditions arising from the closing of the drinking places?" Invariably I have received the answer that the men are more efficient and have applied themselves to their work with more enthusiasm. Furthermore, there has been a greater output the day after payday while the saloons were closed than was ever achieved at any other known period.

Our duty then, not only as coal operators but as plain, ordinary, everyday law-abiding citizens, is clear: Close the saloons and bring out the real efficiency of the men.

Trained rescue crews wearing apparatus, as soon as they arrive at the scene of a mine disaster and have made necessary preparations, should immediately begin to explore the mine in advance of the recovery crews.—*Rescue and Recovery Operations in Mines.*

Continuance and Modification of Government Control*

By F. S. Peabody
Chicago, Ill.

I consider the coal industry the greatest industry in the world. Without coal there could be no real progress. There is nothing in which all of the people of the United States are more deeply interested than in coal. Nothing reaches nearer home than coal, since every person is interested in its consumption, transportation or production. Many thousands of men are employed in its production, and more than 80 per cent. of the cost of producing coal goes to labor.

As Samuel Gompers says, "These men must be kept employed. You cannot get freedom on an empty stomach. To maintain the standard of the American working people will furnish the greatest impetus to progress and civilization; the discontent of the hungry leads only to chaos and inaction."

I further quote from Frank Morrison, secretary of the American Federation of Labor, who says that "regardless of the wishes of any individual or group, any reduction in the present standard of living will be opposed. By standard of living I refer to substantial food, housing and all necessities to well-ordered living."

Labor is interested not alone in the dollar, but in how many things can be bought with the day's work. The world war has brought new responsibilities to everyone —to the employed and the employer. I see no difference between the great labor leaders and the great industrial chiefs. Both have been dreamers and idealists. One group has been dreaming and acting on the extension of industry and the returns on invested capital, and the other group has been dreaming and acting on the welfare of the people they represent; but under our new responsibilities, both must look at the other's side and meet on a common ground.

I view with great concern the departure from the capital of such men as Schwab, Ryan, Garfield, men possessing an intimate knowledge of the industries which they have been directing, and turning their work over to bureau chiefs, who though their intentions are

*Address before the Reconstruction Congress held under the auspices of the United States Chamber of Commerce, Atlantic City, N. J., Dec. 4, 1918.

of the best have not the broad vision and industrial experience of the big business men of the country.

I view with equal alarm the departure from the country of such men as Gompers and other labor leaders at this critical period, as their advice and counsel are needed on the great questions that this country must solve at this crucial time.

I believe that the Fuel Administration should be continued until peace is proclaimed, and strongly favor a continuation of the zoning system and price regulation until the Lever act ceases to operate.

Under the Lever law there are two important industries that were taken control of by the Government —food and fuel production. The Government made a contract with the farmers for wheat at $2.20 a bushel, and this contract covers not only the wheat in existence today, but the crop of next year, yet unplanted. What would be the result of the breach of this contract? Chaos and almost revolution. The Government made a contract with the union and nonunion miners to pay a definite rate of wages up to the time that peace was proclaimed. The Government made a contract with the coal operators, authorizing them to charge certain definite prices for coal, provided they carried out the Government's agreement to pay the wages the Government had contracted to pay the miners. Nothing but chaos could result from a breach of this contract—the shutting down of industry, congestion of railroads, and the necessity of a readjustment of wages during the most critical period in the industrial history of the United States.

Sherman Law Responsible for Waste

So far as price and distribution of coal are concerned, the Lever bill has suspended the Sherman anti-trust law, but with the proclamation of peace the Lever law will automatically cease to exist. We cannot go back to the survival of the fittest policy, which has resulted only in ruin and destruction in the industry.

The Federal Government, states or municipalities should not own or operate fuel facilities, except distributing facilities at isolated points, and then only when it is impossible to have such facilities operated by those in the industry. The individual who has made a life study of coal production can operate mines better than the Government.

Congress should be asked to reassemble and reconstruct the present laws prohibiting the combination of trade, commonly called the "anti-trust" laws, and make them clear, reasonable and adequate.

The Sherman anti-trust law is responsible for the heavy loss of life and the wasteful methods of mining under which approximately 50 per cent. of the natural resources of the country are ruined for future generations. All of us are extremely anxious to protect the lives of our workmen by the installation of every known safety device. Our workmen are entitled to this, but the installation of such devices involves the investment of millions of dollars, with no assurance of return of either principal or interest, as the Sherman law prohibits a discussion of competitors' prices which should cover cost and returns on investments.

None of us favors the wasteful methods of conducting our mining operations, and all would be willing to employ methods under which practically all of the coal would be recovered; but this would involve heavy investment over long periods before any return could be expected. Under the operation of the anti-trust law no return is assured.

The President has gone abroad to make certain that the peace which is established shall put an end in international trade to the old system of unrestricted cutthroat competition between one nation and another. To insure this result, he is advocating new standards of international policy and international trade, with some effective agency to maintain these new standards. Examined in detail, his program means international division of markets, international control of raw materials, with prices in international trade that are fair as between nations. His trip to France is a recognition of the fact that such results in international trade are impossible under unrestricted competition. If it is necessary to adopt such measures in international trade, surely the need in domestic trade for such control is equally evident; yet this is forbidden under the provisions of the Sherman Act.

Abandoned Gas Wells

When nature favors a section with both coal and natural gas, she introduces difficulties for the coal operator and gas driller alike. In regions where coal and gas are being exploited at the same time it is essential that a thorough understanding exist between the coal and the gas operator if difficulty is to be avoided. Many gas wells have been put down throughout the northern part of West Virginia, and in part of this territory where coal is being developed extensively systematic plugging of exhausted gas wells has been established.

In drilling the well, a 16-in. hole is put down for a distance of at least 50 ft. below the Pittsburgh seam. This hole is then lined with 3 in. of cement, which reduces its diameter to 10 in.; drilling then continues at this latter diameter. When the well is exhausted, a wooden plug the diameter of the hole and 3 ft. long is put in the well and forced to the bottom; on top of this is placed a lead plug of the same dimensions. This combination wood-and-lead plug is repeated 500 ft. higher up in the hole, some branches of a tree having been rammed down to offer an impediment to the descent of the wooden piece at the required distance. As before, a lead piece is put in on top of the wood, after which some 20 ft. of crushed rock and sand are placed.

At a distance of 500 ft. above this second plug the operation just described is repeated, and the plugging of the abandoned well is complete. It is essential that great care be exercised in all operations connected with gas wells in active coal fields. Should the protecting coal pillar become crushed or even seriously cracked while the well was delivering large quantities of gas, the mine workings immediately around the well would be quickly filled with the gas. A similar disaster might even occur after the well was supposed to be quiet, should a flow of gas start up again and find a way into mine workings.

All you need is a heart and a dollar. Are you helping the Red Cross in its noble work?

Some Characteristics of American Coals in Byproduct Coking Practice—II

By F. W. SPERR, JR.
Chief Chemist, The Koppers Co., Pittsburgh, Penn.

SYNOPSIS—*Conservation is served by the use of the byproduct coke oven, as the best coals formerly coked in beehive ovens are no longer essential for this purpose. High-grade, low volatile steam coals are reserved in many cases for the use for which they were intended, and mixtures of inferior coals substituted—the resulting coke being entirely satisfactory. The study of the behavior of various coals in the coking process (on a practical scale), of the quality of the coke produced, the yield of byproducts and the details of oven design and operation are touched upon.*

THE sources of the coal now being used for byproduct coking are remarkably localized. The great bulk of the supply comes from the bituminous and semi-bituminous beds of the Appalachian trough as mined in Pennsylvania, Virginia, West Virginia, Alabama and eastern Kentucky. Although some byproduct coke has been made from Illinois and Indiana coals, and an important plant will soon begin operation upon Colorado coals, the enormous reserves of good coking coals in the interior, Rocky Mountain and Pacific coast provinces have scarcely been touched by the byproduct oven in a commercial sense.

The present tendency is to use less of the expensive semi-bituminous coals—Pocahontas, Somerset, etc.—and to coke mixtures containing much larger percentages of bituminous coals, the volatile matter in such mixtures being from 30 to 35 per cent. The percentage of low volatile coal runs in usual practice from 15 to 30 per cent. Very fortunately it happens that not only do such high volatile mixtures produce larger recoveries of byproducts, but the coke itself is usually found to give better results in the blast furnace, the decrease in coke consumption per ton of pig iron being in several cases quite marked. Fig. 1 shows coke of an excellent quality now being regularly made by the Koppers ovens of the Minnesota Byproduct Coke Co. from a mixture of Pittsburgh and Elkhorn coals, containing no low volatile coal whatsoever. Of the commonly used bituminous coals, the most important come from the Pittsburgh, Freeport and Kittanning seams in Pennsylvania and West Virginia, and from two or three remarkable seams in eastern Kentucky, of which the Elkhorn is the most conspicuous. H. A. Kuhn estimated that in 1912, 75 to 80 per cent. of all the iron production of the United States was located tributary to the coking coal of the Pittsburgh district, and, although this condition has to some extent been modified by the subsequent enormous development of the new Kentucky coal fields, it is probable that the Pittsburgh district still holds the lead over any other as a source of byproduct as well as of beehive coke.

The study of the behavior of various coals in the coking process, of the quality of the coke produced, of the nature and yield of the different byproducts, and, finally, of the adaptation of oven design and operation to produce the maximum value in byproducts consistent with the manufacture of good coke, is a real science, the importance of which can readily be recognized. A description of the large organization and equipment which is devoted by The Koppers Co. to the furtherance of this special science would make an interesting chapter in itself.

It is this science that has made possible, during the last ten years, the rapid and at the same time steady progress in oven construction, without the haphazard design of costly alterations of the previous decade. The engineering feat of building a battery of coke ovens out of several different kinds of refractory materials, of most complicated and varying coefficients of expansion, so adjusted and coördinated that, although the total longitudinal expansion of the battery when heated to operating temperatures is nearly 4 ft., every oven wall is straight and every flue is gas-tight—such a feat is being repeated so many times that we are apt to lose sight of the high degree of skill involved. Something possibly more remarkable is the uniform and correctly proportioned heating to temperatures ranging considerably over 2000 deg. F., by gaseous fuel, of more than 700 sq.ft. of interior wall surface per oven—or, let us say, 50,000 sq.ft. in a battery of seventy ovens. Yet even such accomplishments will often fail if we neglect the investigation of the coal which the ovens are expected to handle.

FIG. 1. COKE MADE FROM PITTSBURGH SEAM COAL MIXED WITH 20 PER CENT. ELKHORN SEAM COAL

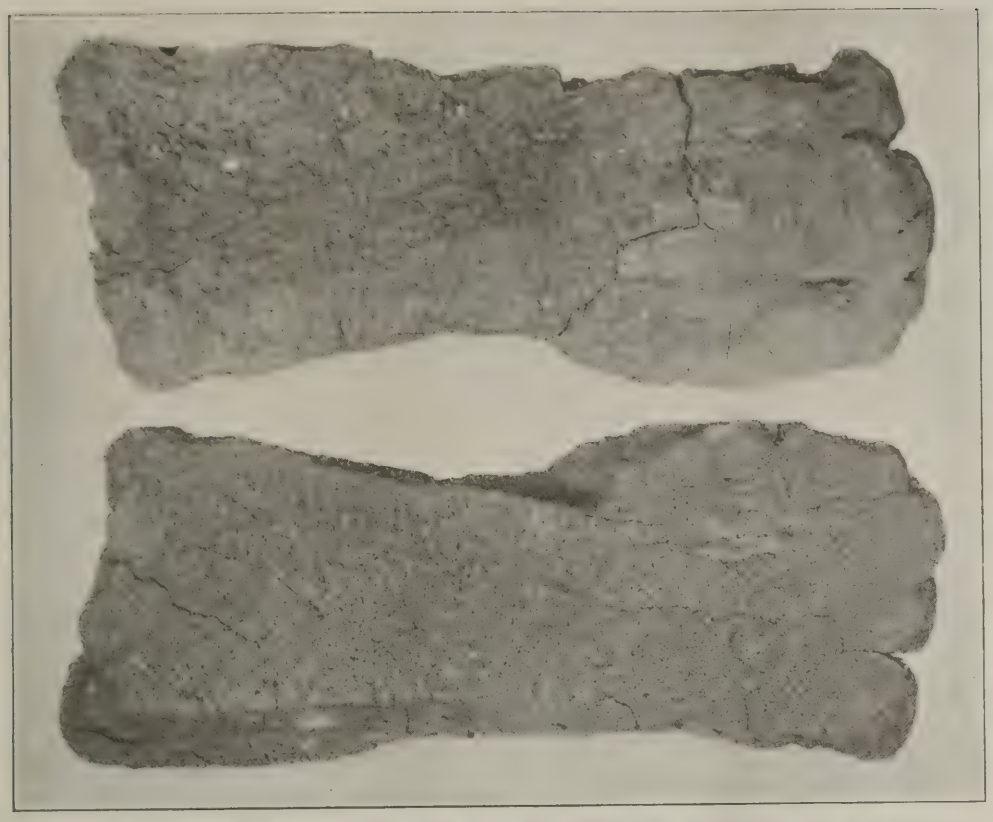


FIG. 2. BLOCK OF TYPICAL COKE FROM COALS OF PITTSBURGH DISTRICT

It is well known that the ordinary methods of laboratory investigation of coal—proximate and ultimate analysis, determination of calorific value, etc.—do not afford much assistance in obtaining information about the coking quality. From a general commercial standpoint some of them—*e.g.*, determination of ash, sulphur, and phosphorus, composition and fusing point of the ash—are indispensable. All of them have their place in adding to the sum-total of our knowledge of coal, and the writer believes that anything, no matter how remote its apparent application, that adds to that knowledge will, in the long run, aid in a more thorough understanding of the coking quality. As has been shown by the painstaking work of Doctor White, of the United States Geological Survey, a study of the amount and nature of combination of the oxygen is especially promising in this connection. No practical substitute has yet been found for the actual distillation of the coal under conditions simulating those that occur when it is coked on a large scale. This is not so easy as it sounds, because the conditions are very complicated, and very insignificant modifications of them in the laboratory lead to the most erratic results. The idea is widely prevalent that ammonia, tar, benzene, toluene, naphthalene, cyanogen, etc., are in the coal, the same way that iron is present in hematite or calcium oxide in marble, and that all the chemist has to do is to "analyze" the coal, to find out the amounts of these substances it will produce when coked in a byproduct oven. Such an idea is far from the truth. Coal contains merely the elements that under certain conditions of heating may go together to form these and other substances; but it no more contains these substances originally than an acre of uncultivated soil contains wheat or potatoes. The amount of variation possible in the yields of byproducts under different conditions is quite analogous to the variation possible in crops per acre of soil, depending upon fertilization, temperature, rainfall, etc. Most published results of laboratory coal distillations are on this account almost valueless for comparison with byproduct coke-oven practice.

The extraordinary possible variations of quality and yields of byproducts might make laboratory investigation seem almost hopeless, were it not for the fact that in almost every case we can fix one fundamental rule; namely, byproducts both in quantity and quality must be conditioned upon the production of a satisfactory coke.

In our methods for testing every sample of coal proposed for use in a byproduct coke oven, the conditions

FIG. 3. COKE FROM 100 PER CENT. ILLINOIS COAL (DISTRICT 6, BED 6)

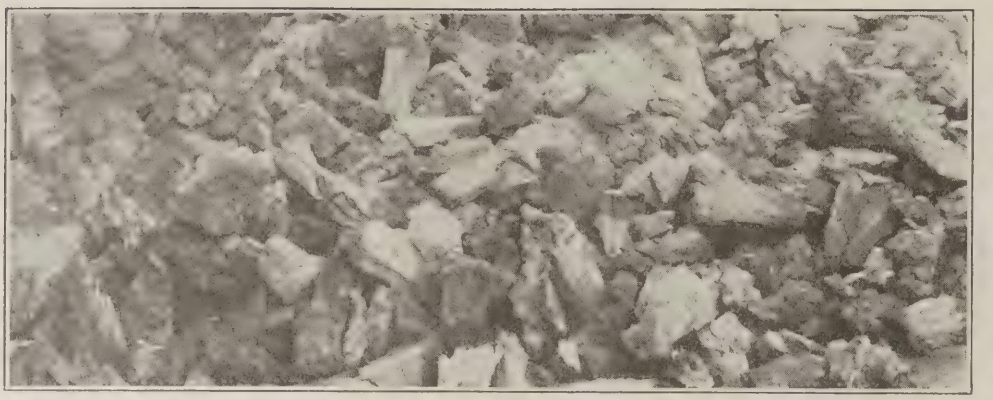

FIG. 4. COKE FROM UNMIXED COAL, PITTSBURGH SEAM, LOWER CONNELLSVILLE DISTRICT, FAYETTE COUNTY, PENNSYLVANIA

of distillation are adjusted according to this rule; and we are able in each case to predict to a reasonable degree of certainty the behavior and products of any coal in our type of oven. The yields of byproducts can be determined very satisfactorily by this method in the laboratory, but any estimate of the quality of the coke must be checked by an oven test. The oven test is desirable, not only to ascertain the character of the coke made under ordinary operating conditions, but also to determine how these conditions must be varied in order to produce the best possible coke from the coal in question. As has been pointed out in a previous article, the possibilities of making coke conform to a desired standard, by proper preparation, oven construction, coking regulation, and, as a last resort, mixture with some other coal, are remarkably great—much greater, in fact, than is generally supposed. The mistake of rejecting a coal for coke-making purposes on account of poor results obtained from a single test should be carefully avoided. Some illustrations of cokes made from coals from a number of the best-known American coal fields are given in Figs. 2 to 8. Fig. 3 is shown by courtesy of F. K. Ovitz, of the United States Bureau of Mines, who has written a very interesting bulletin on coke from Illinois coals.[1] These illustrations are characteristic of the fingery or "pebbly" coke that is very likely to be produced from a coking coal of high oxygen type. As a rule, such coals require more careful adjustment and regulation of conditions in order to produce a satisfactory coke than is necessary in the case of the commonly used coals of Pennsylvania and West Virginia, which contain about the same percentage of volatile matter, but less oxygen. A typical block of coke made from coals of the Pittsburgh district is shown in Fig. 2. The other pictures show the various cokes as they appear on the bench onto which the product of each oven is emptied from the quenching car. Fig. 8 is of some special interest because it shows an excellent coke made from a Nova Scotia coal which contains nearly 40 per cent. volatile matter. Each of these illustrations should be considered individually rather than as broadly typical, because the cokes were

FIG. 5. COKE FROM UNMIXED COAL, ELKHORN SEAM, KENTUCKY

FIG. 6. COKE FROM MIXED WASHED COALS, PUEBLO COUNTY, COLORADO

[1] U. S. Bureau of Mines Bulletin 138.

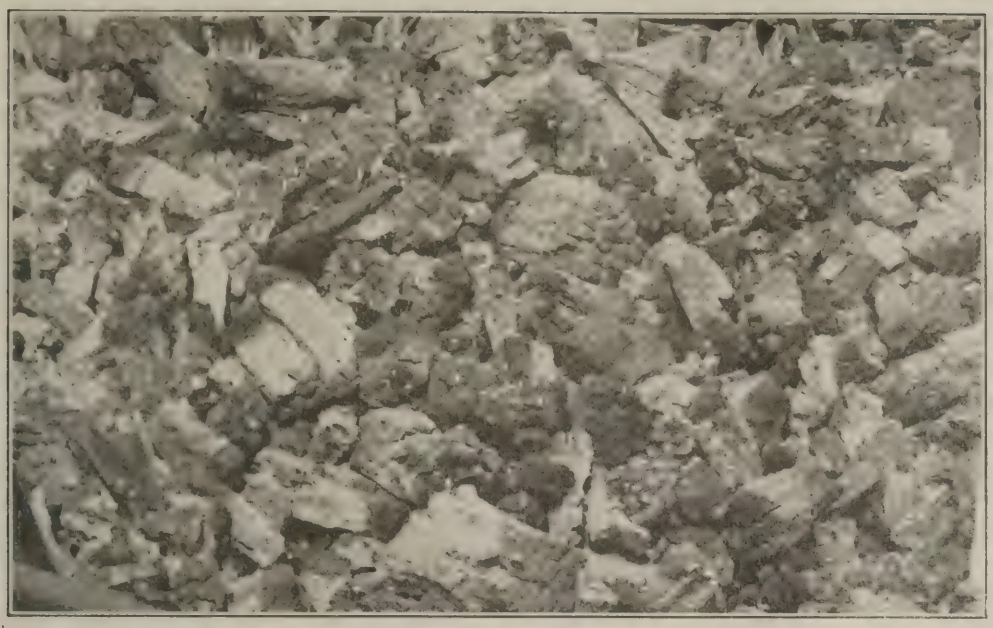

FIG. 7. COKE FROM MIXED WASHED COALS, PIERCE COUNTY, WASHINGTON

made at different plants and for different purposes, and were not intended for strict comparison. There is usually too much variation in the coking quality and byproduct yields of coal from even a small district to admit of the presentation of "typical" samples or data, without the necessity of considerable latitude of judgment. There is sometimes as much variation from mine to mine on the same seam as from coal from two entirely different seams.

There is here a very interesting and virtually unexplored field, namely, the correlation of the geological relations of coals with their coking qualities. There is no doubt that this subject is of great practical importance. A thorough knowledge of it would, for instance, enable us to estimate from simple geological considerations the value of a new mine on a known seam for byproduct coking; or, on the other hand, would assist in defining an unknown seam in new territory from the results of laboratory coking tests. Our present knowledge, however, is much too meager for this. There are a few outstanding facts which will be discussed briefly.

(To be concluded)

Concreting Work in Cold Weather

Occasions arise when concreting must be done regardless of season and temperature. The requirements of successful concrete work under conditions of low temperature are so generally known, says the *Engineering and Cement World*, that the work will be just as successful as though carried on during warm weather. The extra cost on the general run of contracting during such adverse conditions seldom runs more than 10 per cent. of work done in warm weather, and frequently not more than 6 per cent. Part of this extra expense comes from applying protective measures and partly from the lower efficiency of workmen exposed to the cold. Also some of the increased cost may be caused by the added time necessary for the concrete to harden, preventing as speedy progress of the work as under normal conditions. The general opinion seems to be that freezing will not injure concrete which has had an opportunity to harden for at least 48 hours under favorable conditions. Should concrete be allowed to freeze and thaw at short intervals, before early hardening has taken place, it will be damaged. Sometimes concrete will not show any serious effects from once having been frozen if, after it thaws out, it is not again frozen until early hardening is complete. However, it is much better to protect the concrete from freezing for at least 48 hours after it is placed; from four to five days' time would be better. If such protection is given it, little need be feared when the concrete is exposed to freezing weather.

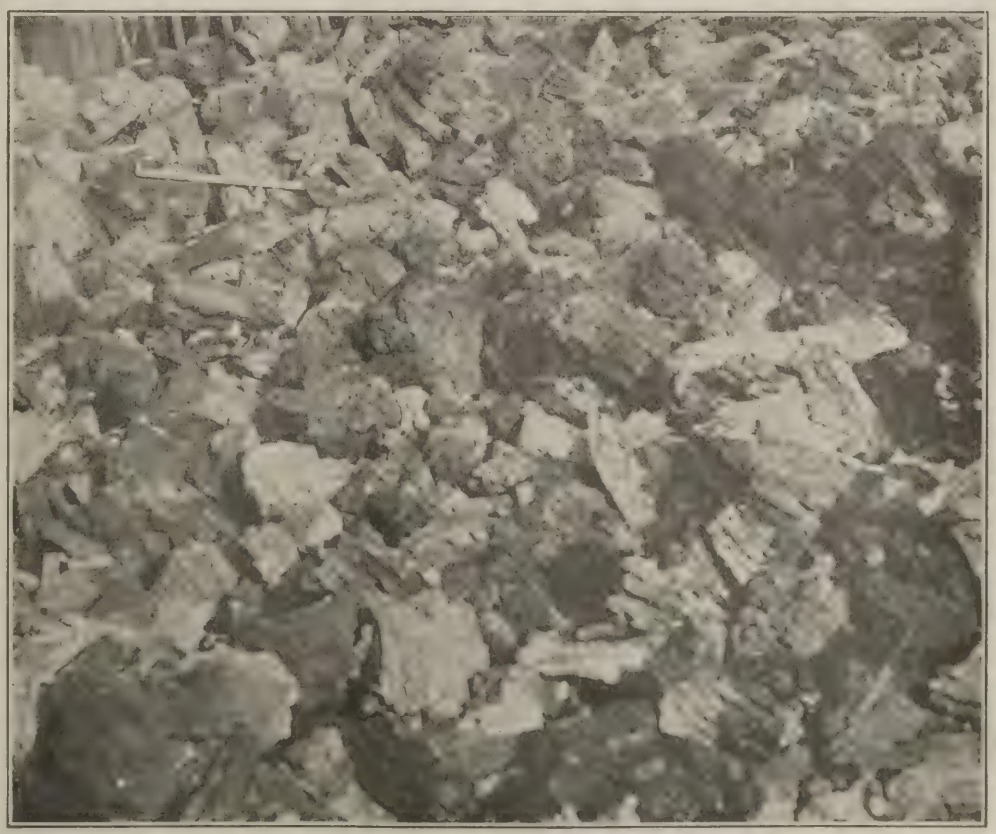

FIG. 8. COKE FROM UNMIXED WASHED COAL, NOVA SCOTIA

Acetylene and Electric Cap Lamps from a Safety Standpoint*

By H. M. CHANCE
Philadelphia, Penn.

SYNOPSIS — *Shows that many of the dangers encountered by miners are increased by lack of lighting. The relative merits of acetylene and electric cap lamps are tabulated, and a suggestion is made that Government experts compile statistical tables based on comparisons of total light by candle-power determinations made under precisely similar conditions.*

THE acetylene safety lamp has been used underground in relatively small numbers and no argument used in this discussion is intended to refer to acetylene safety lamps. This discussion is further limited to the use of acetylene open lights and electric cap lamps in mines that ordinarily are termed "non-gaseous"; that is, mines that produce no inflammable gas, mines that produce inflammable gas in such small quantities as to be practically negligible as an element of danger, and mines that, while producing larger quantities of inflammable gas, can in certain portions be made relatively safe for the use of open lights.

It is, of course, evident that in mines where open lights are used, the danger of ignition of inflammable or explosive mixtures of combustible gas and air from the flame of such lamp is practically the same, whether the lamp be an oil torch or an acetylene lamp. There may be minor differences in the danger of ignition by the flame of an open light, but these differences are small and unimportant.

Defines "Mixed" System of Lighting

It is not proposed to discuss any question of policy as to what is termed "mixed lighting" underground; that is, the use of safety lamps in some portion or portions, of a mine and the use of open lights in other portions of the same mine. Much has been said and written as to the expediency from a safety standpoint, and also from a managerial standpoint, of this use of safety lamps and open lights in the same mine. Where a mine is being worked with open lights used in all working places and the use of a safety lamp is restricted to inspection of working places by the fireboss, mineboss or other officials, such limited use of the safety lamp for purely testing purposes is not considered to constitute a "mixed" system of lighting—this term being used only where safety lamps are used in parts of the mine by the miner for the mining of coal or the driving of entries, etc., while in the same mine other miners are using open lights, or open lights are used by mule drivers, motormen, etc., on the main haulage roads.

It may, perhaps, be sufficient in this connection for the information of those not familiar with the literature on the subject to say that mining engineers, mine executives and miners engaged in coal mining are divided upon this matter and do not seem to be able to reach any conclusion to which unanimous consent can be secured. On the one side we have those who hold that if it be necessary to work any portion of a mine with safety lamps, then the whole mine should be worked with safety lamps and no open lights whatever should be permitted to be used in any part of such mine, and on the other we have those who claim that the use of safety lamps, where necessary in parts of the mine in conjunction with open lights elsewhere, conduces to greater safety than if the opposite policy be pursued. We have also a third class, claiming that under certain conditions the use of safety lamps in the mining of coal should be enforced, while open lights may be safely used upon the main haulage roads over which the coal is transported to the outlet of the mine, and over which the empty cars are returned to the points from which they are distributed to the working places. This subject is one of very great interest and doubtless will continue to be discussed for many years unless discussion be cut short by the enactment of laws requiring the adoption of the use of the safety lamps exclusively in all mines classed as "gaseous" mines.

Danger of Mine Fires with Open-Flame Lamps

Returning to the subject which it is the object of this paper to discuss, it may be well, in advance of a review of the physical differences in the two types of lights under discussion, to outline the elements of danger or of safety in which lighting may be an important factor. Having excluded from the discussion any question of the ignition of inflammable gases or mixtures of inflammable gases and air, by limiting ourselves to a consideration of the use of these types of lamps in "non-gaseous" mines, we have remaining one element of danger which in many cases is of great importance and which must always be increased by the use of any open flame light, whether the light be produced by acetylene, by candles or by any type of oil torch. This is the danger of mine fires.

In mines of all classes in which combustible material exists there is the ever-present danger of mine fires. In many cases this is greater in coal, sulphur and other mines in which the material mined is of a combustible nature than in metalliferous mines or mines working a mineral which is not combustible. Aside from spontaneous combustion, which is foreign to the subject under discussion, the danger of the direct ignition of coal from an open light is comparatively small. Fires in coal mines caused by open lights usually are due to the accidental setting on fire of mine timber, cotton waste, wooden boxes or other material, and not to the direct ignition of the coal from the flame of the light. The origin of such fires in coal mines, therefore is often similar to that of fires in metalliferous mines, in

*Paper read at the seventh annual congress of the National Safety Council, St. Louis, Mo., September, 1918.

which the fire is confined to the timber ring or other combustible material which has been brought into the mine.

It may at this time be well to refer to the common presence in mines of many different types of combustible material which are brought into the mine for various purposes. Where mules are kept underground we have, of course, hay and grain and the straw used for bedding, which frequently have been the cause of serious mine fires. In many mines we also have oil houses and lamp houses underground, in which oil for the lamps and lubricating oil for machinery is stored, and engine houses where machinery (such as pumps, compressors, fans, etc.) is used underground. In addition to the oil there is usually cotton waste, which is, of course, universally recognized as an element of danger. While the present practice in many districts is to discontinue the use of wood, so far as possible, in the construction of permanent inclosures underground, such as engine rooms, oil houses, stables, etc., the presence of lumber in such construction is an element of increased danger when open lights of any type are used. In addition to these materials we have the timber used for roof support along the gangways, entries, drifts, levels, chutes and haulage and travelingways, and in the working places. In mines where a timber mattress or cushion is used between the ore being mined and the overburden, we have large quantities of inflammable material which may frequently be in danger of ignition from the use of any type of open light. Again, in the working places the miner frequently brings in materials that are inflammable, such as powder boxes and other waste material, and boards or planking for use as shoveling platforms, brattices, stoppings, etc.

Mine fires in metalliferous mines are of course often due to other causes than the use of open lights. The decay of timber, heat produced by the great friction of moving masses during settlement or squeezing, and other causes of spontaneous combustion, have doubtless been responsible for many fires in mines of all classes. In addition to these we have of course the ever-present risk of fire from the accidental ignition of explosives and from the firing of shots in the brooding of the ore or other material mined.

Majority of Fires Due to Carelessness

All of the foregoing considerations apply with nearly equal force to the use of any type of open lights. Where candles, oil torches or acetylene lamps are used there will be some danger of mine fires being started by the flame of such lights. It is useless to argue that the majority of fires so caused are due to carelessness in the use of such lights. The danger in all cases, while similar, is not however exactly equal. In the use of candles we have in addition to the flame the danger caused by the dripping of paraffin, stearine or tallow, and in the case of oil torches a similar increase in danger from the dripping of oil from a leaky lamp or from a lamp or from the wick spout. In the case of the open oil torch we also have the additional danger due to the carriage of oil and the presence of oil in quantity kept underground for the use of the miner, and also that carried by him for supplying his lamp. In the absence of complete statistics showing the cause of mine fires, it is impossible to determine the relative difference in the character of the lights which may tend to increase or diminish this danger.

It will readily be understood that the danger of mine fires from the use of open lights will depend largely on whether the mine is relatively wet or relatively dry or damp. In regions where the air is extremely dry and the mines contain but little water, the timbering is much drier and the risk of mine fires correspondingly greater and the difficulty of extinguishing fires is increased, of course, by the dryness of the timber. This statement applies with equal and perhaps greater force to coal mines, because in coal mines that are relatively wet or in regions where the air is relatively highly charged with moisture, the coal is not so easily ignited by burning props or mine timber of any kind as when the mine is dry or is located in a more or less arid region. It is evident, therefore, that as the danger of mine fires is increased by the use of open lights underground, the electric cap has a decided advantage over any open flame light.

Miner Subject to Many Accidental Risks

In addition to the elements of danger peculiar to mine employees the miner is subject to many of the accidental risks commonly met by men on the surface. It would be beyond the province of this discussion to enumerate the hundreds of kinds of accidents which occur underground. In going to and from his work and in working in the room, chamber or stope in which his principal work is done, the miner is often the victim of an accident that may be designated as belonging to the "self-inflicted" class. In this class may be grouped all those accidents resulting from the use of tools employed in mining. The miner may accidentally strike himself or be hit by some flying fragment of coal or ore, be injured with a pick, may become entangled by machinery, or receive injuries from electric shock—there are many ways in which he may accidentally cause injury to himself or a fellow employee. He may injure himself by tripping over an obstacle, by falling down some hole, winze, shaft or other excavation, may be run over by a mine car, kicked by a mule, fall from a scaffolding or ladder, to illustrate that general class of accidents which are due to the voluntary or involuntary act of the employee which are avoidable. In many cases they are due to carelessness on the part of the miner or a fellow employee and do not belong to that class of accidents which are due to the risks peculiar to underground work. We may include in this class many accidents due to shots that have missed fire, to the presence of explosives in ore or coal which is being loaded by the miner, and many others which will be found in the reports of the mine inspectors in the states in which mining is conducted on a large scale.

I have not had the time to compile lists of accidents which belong to the class which has been described above as due to the voluntary or involuntary act of the miner or fellow employee and which are not due to dangers which are peculiar to underground work, but he is of the opinion that such compilation, if made, would show that most accidents underground belong to this class and that a much smaller proportion will be found chargeable to conditions which are peculiar to underground work.

I also believe this class of accidents is more important than that of all other classes combined and should be given prominence in any discussion, from a safety standpoint, of the use of the acetylene light as compared with that of the electric cap lamp.

It will probably be admitted without discussion that the risk of accidents resulting in injury or death to the miner will decrease as the efficiency and volume of light is increased. There can be no question as to whether accidents of this class occur more frequently underground than on the surface. The principal (but not the only) reason why accidents in this classification are more frequent underground than at the surface is undoubtedly due to the difference in the amount of light and in the illumination of the tools, etc., being used. It is also true that accidents of this class, underground, are increased over those that occur in similar work at the surface, because of less efficient supervision by foremen and supervision by foremen and superintendents as to the condition under which the individual employee is working. Neither the mine foremen, mineboss, or superintendent can continuously be present to supervise the work of the individual employee to notify him to avoid risks of injury, or to reprimand him for obvious carelessness. Therefore it is evident that the increase in accidents of this class underground is not entirely chargeable to deficiency in illumination, but is partly due to the impossibility of exercising as efficient supervision underground as at the surface.

As increased efficiency in illumination—that is, increase in the light furnished the individual employee—will materially reduce the risk of accidents of this particular class, it is evident that the acetylene light is superior to the electric cap lamp of the type and candlepower ordinarily used; also that the acetylene light is better than oil torches or candles, because of the greater illumination which it affords.

Reasons for Use of Acetylene Lights

The miner using an acetylene light is less likely to stumble, fall, or come into contact with electric wires, be run down by mine cars, injure himself or a fellow employee with hand tools, implements or machines used in mining; is less likely to miss his footing in climbing ladders or traveling winzes or stopes not provided with ladders, than if he were doing these things with the light afforded by the ordinary electric cap lamp.

In speaking of accidents peculiar to mines, it is not intended to include accidents due to the explosion of combustible gases, the burying of miners by accidental caving or squeezing whereby the travelingways leading to the surface are closed, accidents due to the flooding of mines, or to any cause not affected by the method of illumination.

The principal cause of those accidents underground are due to the falling or caving of the roof in working places or on the traveling or haulageways along which the miner travels and through which the material mined is transported. These accidents, generally, are not due to any direct act of the miner or his fellow employee but arise from some weakness in the material forming the roof or to a failure to recognize such weaknesses and to take measures to avoid the danger. This danger is present to a greater or lesser extent in all mines, but under some systems of mining it is reduced to a negligible factor by the method by which the material is mined; for instance, in the system where a mattress or cushion is used between the material being mined and the overburden, there is, of course, no direct danger from falling roof; the danger in such cases is from a general caving in or squeezing.

In addition to the hazard caused by a weak roof, or an insufficiently timbered roof, there is the danger of falls from material being mined. Where deposits inclined at a high angle or pitch are being mined the danger is principally from this cause and not from the roof or hanging wall of the deposit. When the deposit is relatively flat and of considerable thickness, there is danger of fragments falling from the walls or face of the material.

While this phase of the risks peculiar to work underground is of importance in connection with any consideration of the system of illumination used, it can be dismissed with very few words, because it is evident that the risk of injury will be reduced by an increase in the illumination of the working places, or of places where such roof falls or falls of material are likely to occur. The subject, however, is one which could be discussed at great length in its various bearings.

Value of Intensive Lighting Underground

The advantage of high illumination in working where the roof or the material mined constitutes an element of danger from falls has been recognized in many districts by the installation underground of electric arc systems of lighting, by which it becomes possible to more thoroughly inspect the roof from time to time and to more quickly detect dangerous conditions which may develop. Further, the use of such intensive lighting is of great advantage in prosecuting the work of removing the danger, either by the removal of loose material or the placing of supports to greatest advantage in places showing, or likely to develop, weakness.

The same principle applies to taking care of the roof in the rooms or chambers of coal mines, and in small stopes of mines working ore deposits, and it is evident that the high candlepower furnished by the acetylene lamp will contribute to the safety of the miner and his fellow employees, not only by enabling him to more readily and surely detect any dangerous condition at or near the place where he is working, but will assist him in setting his props or other supports in the best position to reduce this danger to a minimum. Failure to set such props or supports in the best position, or in a position where the prop gives such support as will remove the danger, is a frequent cause of accident, due to the fact that the miner having set the prop, or props, and believing that he has placed them properly, will then perhaps unnecessarily expose himself to greater risk than if he had taken no measures to prevent the roof from falling.

Unfortunately, there are no records available showing whatever difference there may be in the number of accidents from roof falls in mines worked with safety lamps (which, of course, give very small and inefficient illumination) and mines working under similar conditions as to roof in which open lights are used. I have suggested to the Bureau of Mines that statistics of this kind should be obtained, because this has an

important bearing upon the expediency of using safety lamps, and I understand that measures will be taken to secure such data. It must, however, be some years before sufficient information can be compiled to be useful in drawing conclusions as to the increase, if any, in roof-fall accidents which may be traced to the use of safety lamp illumination.

In the absence of these data it is of course impossible to say how much higher illumination of the acetylene light over that of the ordinary electric cap lamp will increase the safety of the miner in relation to accident from roof falls and falls of ore, coal or other material.

The acetylene lamp is objected to by some because it does not give as early warning of a deficiency in oxygen in the mine atmosphere as that given by an oil flame lamp, but by others this peculiarity of the acetylene flame is regarded as furnishing an added element of safety. The difference in the action of oil and acetylene flames in an atmosphere deficient in oxygen may be compared to the customary use by our railroads of green and red as danger signals. The green signal means, "Danger ahead, proceed with caution." The red signal means, "Danger, *Stop!*" One is a caution, the other serves as an imperative order to stop at once.

So it is with the lights. When the oil lamp begins to fail the air is still respirable; the flame may go out and the air may still be respirable—the warning to the miner being cautionary but not positive. Hence, he may walk directly into a deadly atmosphere. When, however, the acetylene flame begins to fail, or is extinguished, the miner knows that the danger is *actual* and is *present* and that he must at once retreat or be overcome.

In mines where atmospheres deficient in oxygen are likely to occur both oil and acetylene flame lamps are safer than the electric cap lamp, for the latter gives no warning whatever of any deficiency of oxygen or of the presence of any poisonous constituent in the mine atmosphere.

RELATIVE MERITS OF ACETYLENE AND ELECTRIC CAP LAMPS

	Acetylene Lamp	Electric Cap Lamps
Weight	Light	Heavy
Length of shift	Can be prolonged	Fixed
Quantity of light	Can be increased above normal	Fixed
	Can be reduced below normal	Fixed
Warning as to irrespirable atmosphere	Gives warning	Gives none
Repairs	Burner can be renewed or cleaned if clogged	*New bulb can be inserted
Mine fires	May be cause of mine fires	Not likely to cause mine fires
	Danger may be reduced by wire mesh guard or mica chimney to protect flame	
Extinguished by shotfiring	Yes (Can be equipped with auermetal or other re-igniter)	No
Debatable uses	In mines where timber is very dry	Can be safely used under these conditions
	In mines where coal is very dry and there is much coal dust	

* NOTE—In the electric cap lamp, as constructed for use in gaseous mines, no provision is made for replacing a broken bulb (or defective bulb)—but the lamp can be so constructed, if desired, for use in non-gaseous mines.

I have not attempted to show the difference in the illumination afforded by these two types of lamps, but may say for the information of those who are not familiar with the subject that the figures of candlepower as given in many publications must be analyzed before making a comparison. If the light, as in the electric and acetylene cap lamps, be concentrated by a reflector to illuminate a certain spherical sector, the light in this section is, of course, of much greater candlepower than if the light be permitted to radiate in all directions. Owing to differences in the reflecting mirrors used for this purpose, both as to design, polish, size and condition, and owing to the difference in the shape of the flame of an acetylene lamp and the incandescent filament of an electric cap lamp, many of the candlepower tests reported by different observers cannot be compared directly. It seems to me that the only fair basis for comparison would be to determine the *total light* by candlepower determinations made under precisely similar conditions, and the *available concentrated illumination* by determinations using the most effective reflectors for each of the two types. I do not know whether this has been done or not. From observations that have come to my knowledge from various sources within the last three or four years I believe that the available illumination given by an acetylene cap lamp, burning normally at average rate, is from three to six times that produced by an electric cap lamp operating under average and normal conditions. The difference in the concentrated illumination may be somewhat less than this, but when the acetylene lamp is operated at its full rate (and many miners so operate them continuously) the difference is often twice that indicated by these figures.

From *The Retail Coalman*

No Wonder Hard Coal Is Scarce!

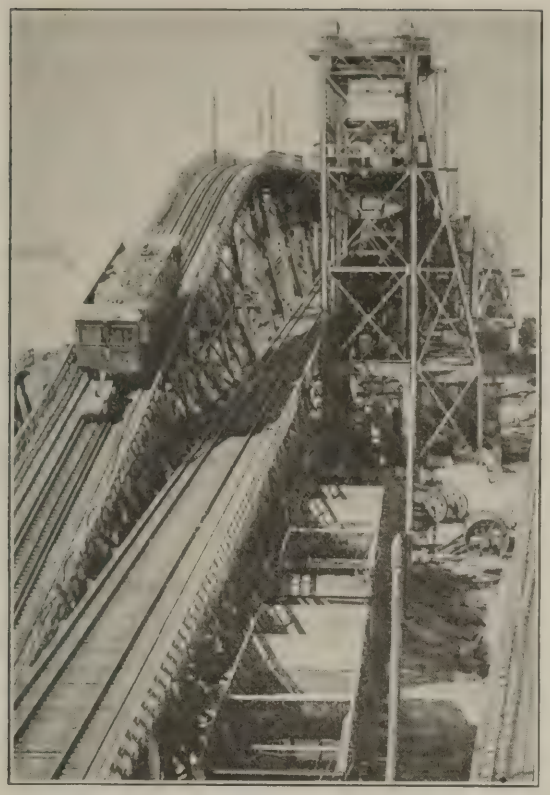
Coal-Handling Plant at Sewalls Point, Virginia

New Facilities of Virginian Railway at Coal Pier near Norfolk Also Include Cars of 120 Tons Capacity and a Long Incline

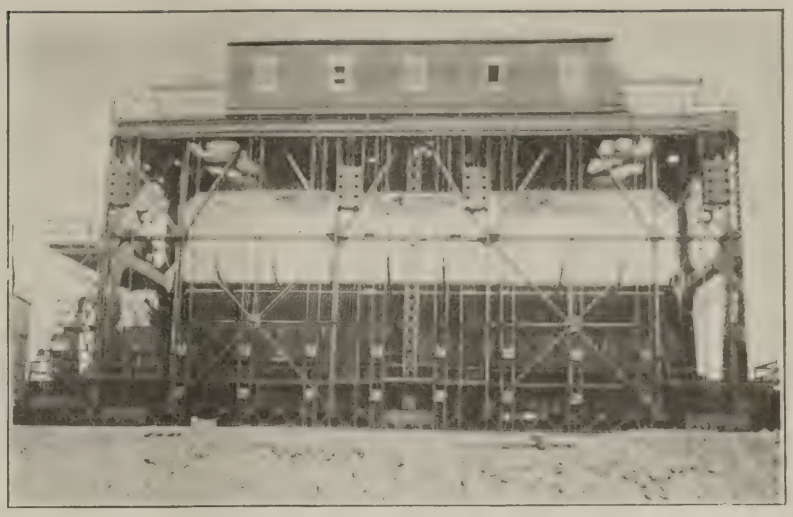
A DOUBLE car dumper, with pier cars of 120 tons capacity and an elevator to raise them to the top of the pier, has been added to the facilities of the coal pier of the Virginian Ry. at Sewalls Point, near Norfolk, Va. They supplement a single dumper, pier cars of 60 tons capacity and a barney incline from the dumper to the top of the pier, installed in 1909, when the pier was built, and increase the capacity of the plant from 1500 to 3000 tons per hour. The operation of the pier is the same as before, the pier cars for both dumpers running out to the end of the pier by electric power on the outside track and returning down the inclined center track.

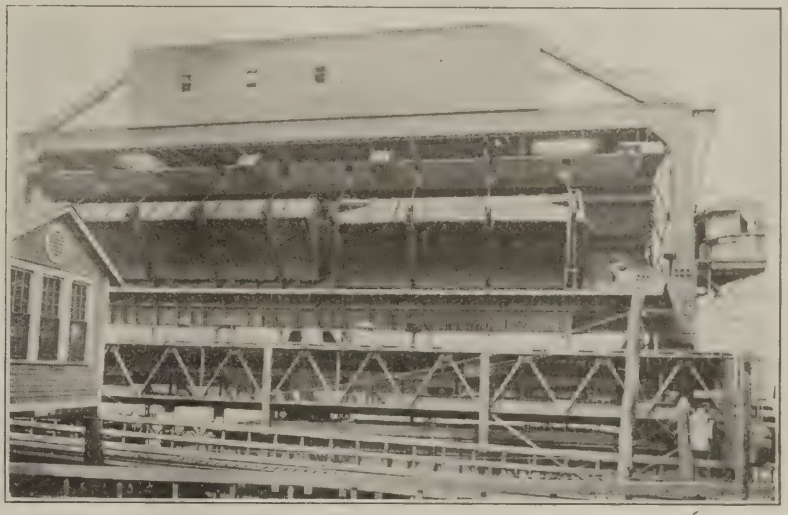
The double car dumper is the first built to overturn two ordinary road cars at a time. It is 94 ft. long between end posts. The car rails are carried on a movable platen which rests on rollers in the bottom of the cradle —or, in fact, two platens, end to end, one for each car. When the cars are on the dumper the platens are moved laterally until the sides of the cars come securely against the side of the cradle for support. When the two cars are of about the same width it is not necessary to uncouple them, but when they are of different widths the two parts of the platen can be operated separately. Eight clamps are operated independently by counterweights which travel in guides at the rear of the machine. They are so spaced that they engage various lengths of cars and are automatically adjustable to any height or width of standard railway car.

The machinery for rotating the cradle is located on top of the main structure, where it is free from dust and accessible for repairs. After the cars have been properly placed on the cradle, the rotating mechanism is started and the cradle with the cars is revolved until the cars are inverted to an angle of 20 deg. with the vertical. The clamps as well as the cradle are counterweighted, this facilitating the return of the cradle to its former position.

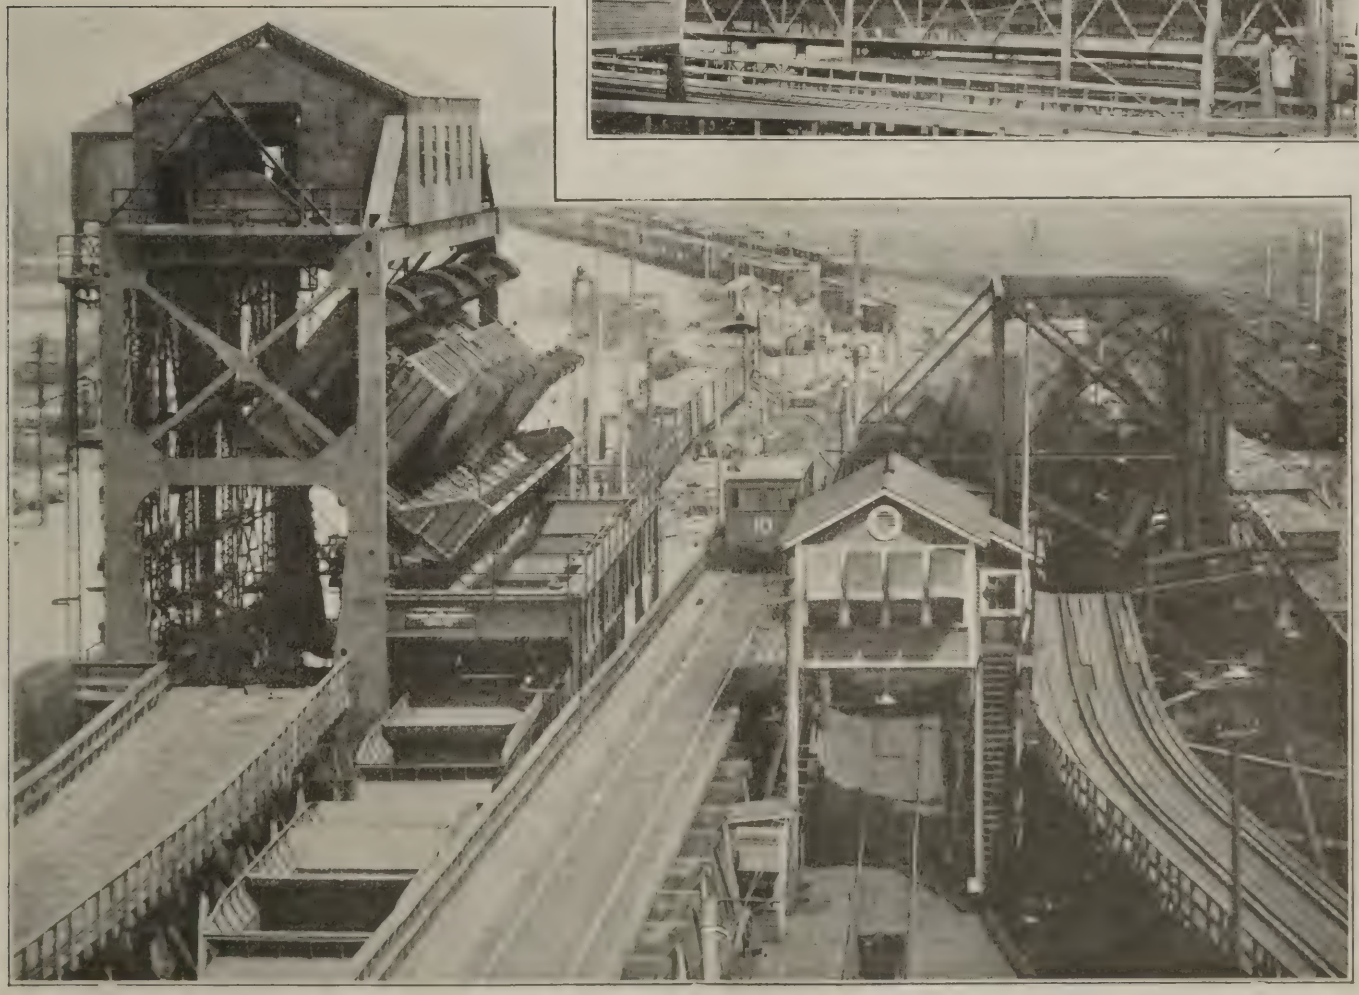


Coal dumped from two cars end to end is distributed over a maximum length of about 88 ft. This is much greater than could be gathered in the hopper of a transfer car, which in this case is about 51 ft. In order that all the coal from the road cars shall be properly discharged into the transfer cars without resort to a concentrating chute, which would at once result in an extreme drop of the coal, two steel apron conveyors are provided, each about 8 ft. wide and 34 ft. long, supported horizontally in a portal frame in front of the car dumper. A clear space of about 36 ft. is left between the conveyors, which form a portion of the bottom of a hopper into which the road cars are dumped. The longitudinal center of the conveyor is located directly over the center line of the transfer-car track. With this arrangement all the coal that falls on the conveyors is transferred horizontally and discharged into the transfer cars.





ONE OF THE LARGEST COAL TRANSFER CARS EVER BUILT—CAPACITY 120 TONS



Two 275-hp. motors, designed to work on a direct current of 550 volts, operate the cradle, working through four drums geared by three reductions of cut spur gears.

As the cradle is rotated the contents of the car are gradually discharged over the edge of the apron plate, into the receiving hopper which carries the conveyors. This hopper, for a distance of 36 ft., is open at the bottom, and the coal is discharged directly through it into the transfer cars. The conveyors are interlocked with the cradle, so that when the rotation starts the conveyor motor is also started, and the conveyors are

TWO GENERAL VIEWS SHOWING OLD AND NEW FACILITIES SIDE BY SIDE, AND TWO VIEWS OF NEW DUMPER HANDLING TWO ORDINARY ROAD CARS AT ONCE

in full operation when the first coal falls on them. They are both operated by one 80-hp. motor.

A disappearing barney, which on the return trip, when near the bottom of the incline, follows a low-level track into the barney pit so that cars can be let down by gravity from the load yard before the barney is in position, pushes the road cars up to the dumper. Both the barney and the dumper are operated from a cab at the incoming end of the dumper. All of the speeds and the motions of the dumper are regulated to produce a complete cycle in two minutes.

The dumper will handle at once two cars of 60 tons capacity, or one of the new 110-ton hopper cars of the Virginian, which weighs 160 tons when loaded.

Transfer cars of 120 tons capacity—just double that of those originally installed on the pier—take the coal from the dumper. These cars, as one of the photographs shows, are mounted on two six-wheel equalized trucks, each of which is provided with a driving motor. The driving motors are of 60-hp. capacity, geared for a speed of 12 miles per hour.

The trucks are spaced 50 ft. center to center under the car, the total over-all length of which is about 70 ft., the height 16 ft., and the width 12 ft. The body of the car forms a hopper divided into three compartments, each having a capacity of 40 tons, the three compartments having a combined length at the top of about 51 ft. Each of the compartments is provided with a double system of discharge gates at the bottom, through which the coal passes into the pockets to the pier. The gates of each compartment are separately operated by an air cylinder located in the end of the car.

The discharge gates of each compartment are arranged in pairs and hinged to the car body at the sides and in the center, in such a manner as to provide two openings 9 ft. long by 3 ft. 8 in. wide. The operating mechanism is so arranged that the gates are securely locked when closed, and they cannot fall open.

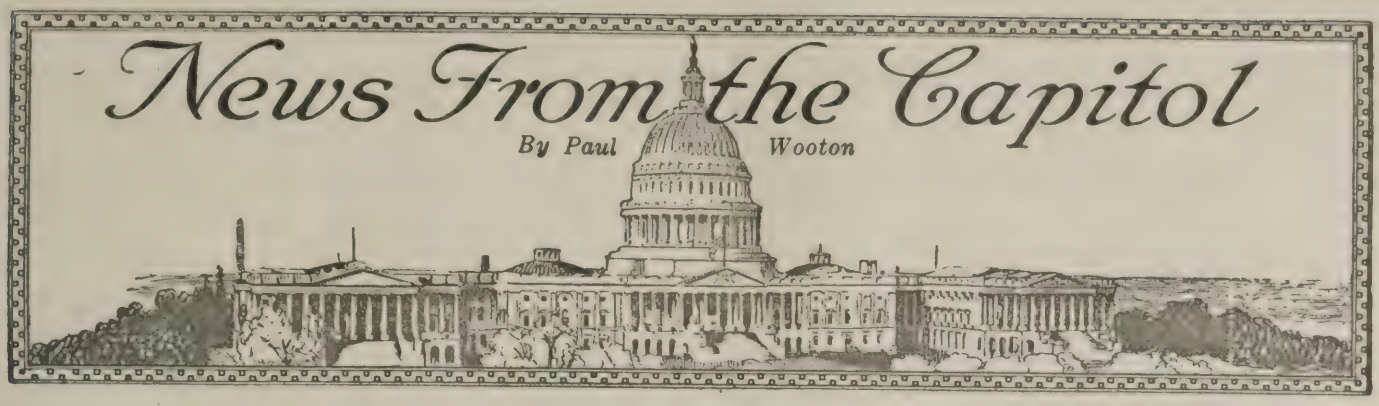
All operations are controlled from one end, although each end is inclosed. The power for operating the cars is supplied from an overhead catenary system. The combined weight of the car and its contents is about 200 tons, making the cars the largest coal transfer cars ever built.

The transfer car elevator raises the pier cars about 67 ft. to the top of the pier. Heavy counterweights are used to counterbalance the weight of the platform and the car; they are so regulated that as much power is required to pull down the empty platform as is required to lift the platform and the loaded car. This arrangement permits the use of smaller motors than would otherwise be necessary.

The elevator is operated by two 450-hp. motors using a direct current at 550 volts. The gearing of the elevator is proportioned to produce a complete cycle in two minutes.

Connecting the frame of the elevator to the pier is a hinged run-off girder, introduced to insure perfect alignment of the rails on the platform and the pier. This girder is hinged to the pier in such a manner as to permit of a vertical movement of the free end amounting to about 2 ft. The free end of the girder rests on brackets on the elevator frame, from which it is lifted by projecting lugs on the platform as it comes to the position of its upper limit. This upper limit of travel is accurately controlled by an electric limit switch, geared to the hoisting mechanism. The power is supplied to the trolley wires in this position, and the transfer car passes out of the elevator, over the hinged run-off girder and out on the pier, where the coal is discharged to the proper pocket. The empty car then returns down the inclined track in the center of the pier structure to the loading track in front of the car dumper, taking its regular turn.

These additions to the equipment of the terminal were installed by the Wellman-Seaver-Morgan Co., Cleveland, which company furnished the original dumper. The work was carried out under direction of H. Fernstrom, chief engineer of the Virginian Railway.



Legal Department

RIGHT TO TERMINATE SALES CONTRACT—Mere default by the buyer under a coal sales contract in paying for deliveries does not entitle the seller to cancel the agreement as to undelivered instalments. Delays in making payments do not justify a rescission by the seller where not the result of deliberate intent to break the contract, and not of such character as to amount to a substantial breach of the agreement. (New York Supreme Court, Alden Coal Mining Co. vs. C. L. Amos Coal Co., 171 New York Supplement, 980.)

STOCK IN KENTUCKY CORPORATIONS—Under the laws of Kentucky, stock in a coal corporation cannot be validly issued in return for services unless the fair value of such services equals the par value of the shares issued therefor. Where a single contract was tainted with invalidity by provision for issuance of stock at less than its par value, provision in the agreement for an exclusive coal sales agency was vitiated; the contract constituting an entirety. (United States Circuit Court of Appeals, Sixth Circuit; Detroit-Kentucky Coal Co. vs. Bickett Coal and Coke Co.; 251 Federal Reporter, 542.)

DEMURRAGE ON WATER SHIPMENTS—Provisions in a bill of lading concerning demurrage on water shipments of coal are binding upon the consignee. For a railroad which owned a dock to reserve discharge towers and prefer vessels carrying its own coal was not unreasonable. Therefore, the owner of a schooner carrying a cargo of coal and discharging at that dock, under a clause in the bill of lading giving a double rate of demurrage for detention on preference being given later arriving vessels, was not entitled to double demurrage because vessels carrying coal for the railway company were given a preference. Such provision for double demurrage is to be regarded as applying only when preference is given out of the usual course of business. (United States District Court, District of Massachusetts; Davis vs. Garfield & Proctor Coal Co.; 251 Federal Reporter, 743.)

RIGHT TO FORFEIT COAL-MINING LEASE—Where defendant coal company violated the terms of a lease held by it by failing for five years to develop a mine, the leasing land owner was entitled to maintain suit to cancel the lease. But the right to forfeit a lease in such cases is subject to waiver. So, the lessors, by subsequently treating the lease as still in force lost the right to enforce a forfeiture against the lessee company after it proceeded toward development work in good faith, and avoided further breach of the contract. When two or more persons own land in undivided interests, and make a joint lease of the entire tract, they become partners in the sense that one of them in writing a letter, leading the lessee to believe that no forfeiture of the lease will be insisted upon because of a delay in commencing actual mining production, binds all the owners. (Arkansas Supreme Court, Schmidt-Blakeley Coal Co. vs. Hembree & O'Kane, 205 Southwestern Reporter, 111.)

Year's Work of Bureau of Mines

Summarizing the year's work done by the Bureau of Mines, Van H. Manning, in his report to Congress, mentions the following results from the bureau's accomplishments in matters pertaining to coal mining:

Tests of a new method of signaling danger to miners underground by the injection of an ill-smelling substance into the compressed-air lines supplying mining machines and pumps have given promising results.

Surgeons of the Public Health Service detailed to the mine safety cars of the Bureau of Mines have surveyed sanitary conditions at more than 150 mines, smelters and mining towns, suggested improvements, and given talks on health and sanitation.

Tests of explosives to determine their suitability for use in mines and quarries were continued. Three new explosives were approved as permissible for use in dusty or gaseous coal mines, and six more were added to the list because of their being similar in all respects to explosives already on the permissible list. At the end of the year there were 160 explosives on this list.

An explosive made of liquid oxygen mixed with carbonaceous material was tested for its value in coal mining.

A new station for testing explosives was erected at the experimental mine of the bureau, near Bruceton, Penn., and methods of analyzing explosives were improved.

Coal-mining methods in Oklahoma were studied with reference to the prevention of waste in coal mines on Indian lands.

In coöperation with state mine inspectors, monthly reports on fatalities at coal mines throughout the country were printed and distributed.

Studies of the combustion of fuel and the baffling of boilers were made in connection with boilers for the Emergency Fleet.

In coöperation with the Bureau of Standards, the Roberts byproducts coke oven was tested to determine its commercial worth.

At the request of the United States Fuel Administration, coal mines in Arkansas and Oklahoma were examined and sampled.

As a result of representations made by the Bureau of Mines, Congress authorized the establishment of a Government coal yard, or yards, in the District of Columbia, whence all Federal buildings will be supplied. This yard will be under the supervision of the bureau.

An electric flash lamp, which should be an aid in mine rescue work, was approved for use in explosive mixtures of mine gas and air.

During the year 8851 miners were trained in first-aid and rescue methods at the bureau's mine safety cars and stations as compared with 4828 in the fiscal year 1917.

Causes of 38 mine accidents, 30 in coal mines and 8 in metal mines, were investigated.

The Gibbs breathing apparatus for protecting men from poisonous or irrespirable gases was further developed by the bureau. In coöperation with the Engineer Corps of the Army, arrangements were made for its manufacture for supplying the mining and sapping regiments, and for commercial sale. Six hundred sets were manufactured during the latter part of the fiscal year and manufacture on a large scale continues.

A large number of coal mines were sampled for the Navy Department, and reports were prepared on the quality of coal and the methods of mining and preparing it for market.

Further tests of the explosibility of coal dust from different mines have given additional information on how coal mine explosions can be prevented or limited.

George Otis Smith, the Director of the Geological Survey, makes the following statement in his annual report to Congress:

To meet the regular needs of the War Industries, Shipping, and War Trade boards and the Fuel and Railroad administrations, as well as special inquiries of the General Staff of the Army, the Ordnance bureaus of the Army and Navy, and the Tariff Commission, increased attention has been given to quarterly, monthly and weekly reports of mineral production. Even daily reports on coal shipments are compiled, and in the support of the Survey's coal statistical work the Fuel Administration has largely coöperated.

As a further contribution to the problem of meeting the Nation's fuel requirements, the hydraulic engineers of the Survey are engaged in a country-wide survey of the power situation to determine where water power can be substituted for steam-generated power or where coal can be saved by interconnecting electric plants or systems.

Instruction Station Arouses Keen Interest

Splendid results are being obtained, it is believed, from the instruction station for householders which the Fuel Administration is conducting in Washington. Keen interest is being taken by a large number of visitors anxious to learn how to operate their heaters and ranges so as to get the best results from the least amount of coal. A similar station is to be established in Detroit. Others will be started in cities that will be designated by the state fuel administrators.

Senate Investigation Committee to Visit Hard Coal Regions

That the Senate Committee on Manufactures expects to make a personal inspection of the anthracite coal fields is shown by a resolution introduced in the Senate by the chairman of the committee. The resolution reads:

Resolved, That the Committee on Manufactures of the Senate be, and it hereby is, authorized and instructed to make inquiry into the coal situation, its production, transportation and consumption.

Resolved further, That the said committee, or any subcommittee thereof, is hereby empowered to sit and act during the session or recess of Congress, or of either House thereof, at such time and place as it may deem necessary; to require, by subpœna or otherwise, the attendance of witnesses and the production of papers, books,

and documents; to employ stenographers, at a cost not exceeding $1 per printed page, to take and make a record of all evidence taken and received by the committee and keep a record of its proceedings; to have such evidence, record, and other matter required by the committee printed; and to employ such other clerical assistance as may be necessary. The chairman of the committee, or any member thereof, may administer oaths to witnesses. Subpœnas for witnesses shall be issued under the signature of the chairman of the committee or subcommittee thereof.

Senator James K. Vardaman of Mississippi has been made chairman of the committee. Senator Reed, the former chairman, has been transferred to the chairmanship of the Committee on Public Buildings and Grounds. The change in chairman will make no difference in the prosecution of the coal hearing now in progress.

Coal Exports for October

Exports of coal, in tons, as reported by the Department of Commerce, for October, 1918, and the figures for October, 1917, as finally revised are as follows:

	October, 1917	October, 1918
Anthracite	478,317	456,029
Bituminous	2,615,526	1,888,801
Exported to:		
Italy	31,094	None
Canada	2,157,857	1,660,229
Panama	94,681	17,605
Mexico	11,618	19,186
Cuba	117,615	89,941
Other West Indies	22,173	12,064
Argentina	29,374	None
Brazil	41,707	38,461
Chile	None	36,402
Uruguay	6,776	13,832
Other countries	102,631	1,081
Coke	114,013	118,796

As usual, there were no appreciable imports of coal from any country save Canada. In October, 1917, the imports from Canada were 130,680 tons and in October of 1918, 133,722 tons.

Recent Zone Modifications

Zones F-1 and F-2 have been modified so that coal from all operations along the Louisville & Nashville railroad in eastern Kentucky may move to all points in Indiana located on and east of the Chicago, Indianapolis & Louisville railroad. Such coal, however, must be used for industrial purposes only, but it may move to all points on the lower peninsula of Michigan without restriction.

Rembrandt Peale Resigns as Commissioner to the Tidewater Coal Exchange

Rembrandt Peale, one of the most prominent coal operators of central Pennsylvania, has resigned his position as Commissioner to the Tidewater Coal Exchange, effective Jan. 1. The Tidewater Coal Exchange is a pool of all coals shipped to tidewater ports of Hampton Roads, Baltimore, Philadelphia and New York City, and is one of the most effective measures for saving transportation taken during the war period. The chief offices of the Tidewater Coal Exchange were in the Woodward Building, Washington, D. C.

Mr. Peale has also presented his resignation as advisor and as director of the Bureau of Labor to Dr. H. A. Garfield, to be accepted at the pleasure of the Fuel Administration. Mr. Peale was one of the first men in the Fuel Administration. His long services there commanded the highest regard and respect everywhere.

His administration jointly with John P. White of the Bureau of Labor was the greatest single factor that contributed to the final success of the Fuel Administration. Mr. Peale has earned the gratitude of miners and operators everywhere by his work at Washington during this period.

J. W. Howe, who has been assistant commissioner of the Tidewater Coal Exchange, has been advanced to the post of commissioner.

Placement of Army and Navy Men

Employers seeking university graduates in mechanical, electrical and civil engineering, and in chemistry, and other technical men with several years of practical experience, are invited to make their wants known to the Professional Division of the United States Employment Service, 16 East 42d Street, New York, N. Y. Employers seeking such men are asked to inform the Division of the precise nature of the positions available, as there are a number of thoroughly equipped officers and men in the Army and Navy service who are qualified for responsible positions. The record of each man is carefully investigated before registration is permitted, and only men well fitted for the positions to be filled are sent to employers.

Brief Washington Notes

Coal-saving slogans put out by the Fuel Administration are being used in moving picture theaters as a part of the program to conserve domestic sizes of anthracite coal.

Shipment of 100,000 tons of coal to Holland has been authorized by the War Trade Board. The coal is to be transported on Dutch vessels, which now are lying idle in Dutch harbors.

To do away with certain confusion due to separate orders, the Fuel Administration has codified Virginia coal prices. No changes have been made in the prices or in the boundaries of the district.

At the special request of the President, Dr. Harry A. Garfield is holding himself in readiness to go to Paris to advise with the American delegation to the peace conference in matters pertaining to fuel.

Coal stocks being held by the Army are reported officially as being 1,190,193 tons of bituminous and 235,497 tons of anthracite. There is no intention of putting any of this coal on the market at present.

With the passing of any further difficulties in the fuel situation in Utah and southern Wyoming the assistant district representatives in those areas have closed their offices. Moroni Heiner, of Salt Lake City, the district representative, will look after such matters as ordinarily would have been handled by the assistant representatives.

Many letters are being received at the Fuel Administration urging the continuance of its Bureau of Statistics. Dr. Garfield has recommended that this work be continued under the Geological Survey. The matter, however, is one which must be passed upon by Congress, as the Survey's present appropriations would not permit of the carrying out of such an elaborate statistical program.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

There is still a disposition in the anthracite region to find fault with Dr. Garfield's decision as to the wage increase of the mine workers, especially in the Wilkes-Barre section. The objection is not so much to the scale provided as to the date from which that scale is made to be operative. The mine workers wanted a scale, markedly retroactive, to take effect Oct. 1. Instead a scale was granted which became operative on the day of announcement.

The trouble-making seems to be a clever trick of the insurgents to disturb the union fold. It is a matter of internal politics. The election may be expected to end the unrest by ending the political advantage which may be expected to come from its continuance. When it can no longer disturb the tenure of office of the officials in control we may expect that we shall hear no more regarding the dissatisfaction.

Still about this we shall do well not to be too sure. Trouble may be started for political motives and continue after the possibility of political advantage may have come to an end. On Dec. 7, 500 delegates, representing 30,000 mine workers of District No. 1, of the United Mine Workers of America—a district extending from Forest City to Shickshinny—met at Wilkes-Barre and unanimously declared the agreement negotiated through the Federal Fuel Administration unsatisfactory.

CONVENTION BY DEC. 28 OR ANTHRACITE STRIKE

This meeting urged that a tri-district convention of Districts 1, 7 and 9—constituting the whole unionized anthracite region—be called, Dec. 26, in the hope of securing a more satisfactory wage award. The meeting was stormy, and the delegates so worded their resolution as to provide for a cessation of work on Dec. 28, if their demands for a convention are not recognized. Another meeting is to be held in Wikes-Barre on that date.

The contract miners do not like the Garfield award. They grumble that they were not given an increase of 15 per cent. on the 1917 scale. They receive 40 per cent. on the scale of 1916, and as the 1917 scale conceded 25 per cent. on that scale, the increase from the scale of 1917 to the scale of 1918 only figures 12 per cent. The contract miners would have the increase made 15 per cent. on the 1917 scale.

Of all the men in the northern anthracite region the Plymouth men are loudest in their protests. They have even been discussing a strike to enforce their demands, and the unrest has already actually caused a strike at one plant. A footman had damaged some property and been discharged, and the men, thoroughly worked up over the larger matter of retroactive payment, went on strike for several days. Eventually the matter was amicably settled.

MUST TAKE BACK MUNITION MEN "SIGHT UNSEEN"

Thomas Kennedy, of Hazleton, district president of the United Mine Workers in the seventh anthracite district, alleges that the operators will not hire all the returning workers, but will "pick only the desirable ones," a policy which Kennedy says the mine workers will bitterly oppose.

The mine workers in the ninth, or Schuylkill, region at their annual session increased the salary of their officers 50c. per day from Dec. 1, 1917. They also urged that the Franklin B. Gowan Beneficial Fund, which was collected in part from the miners by the Philadelphia & Reading Coal and Iron Co., be used for the care of children orphaned by the recent epidemic. The Gowan fund predated the passing of the compensation act, and it is said that about $100,000 was on hand when the compensation act came into operation.

The fall of the tonnage in the anthracite region still occasions much anxiety. We are assured that 1017 anthracite mine workers will shortly be relieved from the army. There were 153,092 mine workers in the anthracite region in Apr. 1, of this year. Just how many there are now would be hard to determine, but assuming that the April force was maintained unchanged the addition of 1017 would add only 0.66 per cent. to that number. At best 1 per cent. is the gain to be expected. If these men go back quietly to their work in the mines without celebrations they will add between ½ and 1 per cent. to the output. If, however, there is much jollification by the other 100 per cent., the addition will really not result in increased tonnage. Reports from Camp Benning, Columbus, Ga., show that there are 9 anthracite workers to be discharged at that point. From Camp Johnston, Jacksonville, Fla., it is reported that 48 available hard coal workers are quartered there. Camp Greene, Charlotte, N. C., has 203, and Camp Humphries 17. With 690 men listed for release, under surveys previously announced, this makes 1017 men.

WAS FORMER DU BOIS PRESIDENT UNPATRIOTIC?

In central Pennsylvania the election seems to show that the old leaders have been discredited, a strong campaign having been conducted by the insurgents based on the alleged lack of patriotism shown by the circular of Aug. 26, which condemned the power given to the district manager of coal production, the secretary of the Coal Producers' Association, to act as the arbiter in cases covered by the scale agreement.

In consequence out goes John Brophy, of Nanty Glo, former president, and in goes Frank E. Waite, of Du Bois, former subdistrict president. "On official tabulations of 130 of the 200 locals," says the Du Bois *Express*, "including locals showing strong support both to Waite and Brophy, give Waite a total of 6870 votes and the incumbent 2907. It is believed in Clearfield that final returns will show Waite a victor by about 3500 votes."

The vice presidency seems likely to fall to William McEwan, of Brisbin, as he leads James Mark, the present holder of the office, by about 3000 votes. William Donaldson, of Du Bois, seems surely to have been elected international board member.

BITUMINOUS MINERS STILL WANT WAGE REVISED

The bituminous mine workers are exhibiting restlessness everywhere. They still want an increase in wage proportional to that granted the anthracite mine workers. The mine workers keep inching upon one another. The anthracite region gets an increase because the bituminous region has the bigger pay; then the bituminous region must have an increase because the anthracite region has been conceded one. It is time to call a halt. If there are to be any increases they must go to the peace-industry workers who have been as peaceful as their industries and have received no increases. As has been truly said, strikes are not between capital and labor, but between worker and worker. It is time for the peace worker to strike against the war worker who has been continuously impoverishing him by raising his cost of living. The peace worker has a right to live and keep warm without paying a prohibitive price for coal.

On Dec. 11 a mass meeting was held at Charleroi, near Pittsburgh, Penn., at which it was decided to hold a special convention to which delegates from the locals of the United Mine Workers would be invited, the purpose being to seek a wage increase. The meeting was presided over by Thomas Metcalf, of Findleyville and William Deiler, the candidate for national board member at the general election

held during the week. District President John H. Walker, who heads the mine workers in the Pittsburgh district, told the men why, in his opinion, they were entitled to more wages.

The influenza is still a factor in the bituminous mines of Pennsylvania. It is thought that the tonnage has dropped between 80 and 90 per cent. due to the epidemic.

Roaring Creek Miners Seek Wage Increase

The West Virginia mine workers have only just become unionized. The union is a new toy to be brought forward on every occasion. What good is it unless it furnishes an excitement every minute! So the war being over West Virginia is experiencing a lot of strikes. In the Roaring Creek fields, near Elkins, W. Va., the miners made a demand for an increase in wages to be granted Dec. 2. When that day came they struck. The mines from Belington, in Barbour County, southward to Mabie in Randolph County, ceased operation together. The plants of the West Virginia Coal and Coke Co., the Jenkins Coal Co., the Randolph Coal Co., and the Spates Brady mines were closed down.

Some of the largest producing mines of the West Virginia Coal and Coke Co. are in the strike territory. The managements of the various companies claim that under the regulations promulgated by the United States Fuel Administration they are without authority to increase wages and that there is no prospect of settlement unless either there is a change in the policy of the Fuel Administration or the miners abandon their demand for an increase.

Up to Dec. 12 there had been no settlement of these strikes except at one mine, the Junior mine of the West Virginia Coal and Coke Co. However, no sooner had these men gone back to work than a strike occurred at the mine of the Gage Coal and Coke Company.

Just north of the strike area described is the Boar Run mine at Philippi, Barbour County. The men at this mine struck Nov. 28, and up to Dec. 4 had not returned to work. As result of a meeting held at Scarbro, Monday, Dec. 3, despite the recommendation of President Gilmore and other union officers, over 2000 mine workers employed at the 15 operations of the New River Co., on Loop and White Oak creeks, quit work on Tuesday, Dec. 3. All the men, including the pumpers, left their posts.

The grievance of the miners relates to the payment of the extra $1.40 a day which the Federal Fuel Board awarded to the miners. The miners claim the company has been dilatory in making settlement under this award, and in some instances has not paid the full amount that is alleged to be due to the miners.

Carpenters and others employed by the month about the mines claim that they should share in the award of extra pay. The operators claim that only the day men directly employed in the production of coal are entitled to this extra money. This point was recently presented before Judge Allison Smith of the arbitration board. He declared in favor of the complainants. The operators were not represented at the hearing and for this reason Judge Smith granted them a rehearing.

Want Pay for Work That They No Longer Do

This strike, like the Roaring Creek difficulty, shows no sign of being settled. It has even spread to the mines of the Brown Coal Co., in South Nurral, Fayette County. The men at this mine have gone on strike to get pay for placing cars at the room face, though the company actually places the cars. An extra allowance of 10c. a car was at one time given the miner for each car placed at the room face. When the company began placing the cars the men did not object to the company's activity but objected to losing the pay that the company had paid for the car placing.

Some of the wages paid at the mines of the United States Coal and Coke Co. prove that it pays to be a mine worker. Bosco Spittisch, a coal loader, made $92.07 loading coal the week before last. He worked 6 days. Dock Smith, colored, a cokeyard man also working 6 days made $60.29 pulling coke. Frank Boots, a Pole, a machine runner, made $72.40 cutting coal in the same 6 days. Peter Vuncrivch, a driver made $35.11 in 6 days.

Out of curiosity we have multiplied these numbers by 52 and we find the Serbian apparently earned at the rate of $4787.64 a year, the colored man, at the rate of $3135.08 a year, the Pole at the rate of $3764.80 and the driver, of nationality unspecified, $1825.72. With such wages these men are surely well entitled to be content.

C. F. Keeney, president for district No. 17, has been absent from Fairmont. His work has been directed by H. P. Peters. He is candidate for reëlection and that is conceded to him for he had no rival candidate. Fred Mooney, the secretary in the same district, has undoubtedly been reelected. James R. Gilmore, the candidate for reëlection in district 29, was likewise unopposed.

The Grafton Coal Operators' Association in Northern West Virginia is determined to stamp out the bonus evil. On Dec. 12 a meeting was held at which it was decided to take up the matter with the United States Fuel Administration through the National Coal Association.

Scale for Deadwork Is Still Unsettled

On Nov. 29 a preliminary meeting was held at Fairmont, W. Va., between the operators' committee and the officers of the United Mine Workers of District No. 17. C. H. Tarleton, A. C. Beeson, L. J. Sandridge, C. J. Ryan, J. A. Clark and John M. Wolfe represented the former, and C. F. Keeny was the leading participant for the United Mine Workers. The discussion was as to "deadwork," that is, pay for work not actually involving the production of coal. A general meeting of the Northern West Virginia Coal Association will be called to give the tentative agreement, when made, final approval.

The Fairmont region in West Virginia is again a victim of influenza. The Clark mines in Harrison County have a number of cases and about half the employees of the Tucker mine of the Orr Coal Co. are afflicted with the disease. Adrian, on the Coal & Coke R.R., is so badly smitten that the local physicians and nurses found it impossible to cope with the large number of cases. Outside assistance was sought.

The Kanawha and Pocahontas districts are similarly affected. The Kanawha & Hocking Coal Co. had to appeal to the State Health Department and so did the Superior Coal Co. at Davy in McDowell County. Similar reports come from Kentucky.

In Kentucky great union activity is being exhibited in the Big Sandy River region under W. M. Peters, the vice president of District No. 17. The drive, the mine workers hope, will net 20,000 members. In Illinois, Frank Farrington, president; Walter Nesbitt, secretary, and Harry Fishwick, treasurer, the administrators of the past term, have been reëlected to their former official positions, according to official advices.

Parker Alleges Judge Elliot Was Coercive

Alton B. Parker, of New York City, is counsel for the mine workers in their appeal against a judgment requiring them to pay $720,000 for triple damages and costs in the matter of the suit of the Coronado Coal Co. It will be remembered that in the Federal Court of the Western Arkansas district at Fort Smith, Ark., judgment was given the coal company for $200,000. Trebling this and adding $120,000 for costs, it will be seen, brings the bill to $720,000. The mines of the company are in Sebastian County.

Parker, in his argument, laid his greatest emphasis on Judge James D. Elliot's supplemental charge to the jury. This charge he held to be coercive and purposed to bring about a verdict for the mining company. The charge was delivered after the jury had failed to agree and asked to be discharged. In it the judge gave the jurors to understand that they would not be released from duty until they had reached a verdict.

This was coercive, he argued, because the trial had occupied a month and the jurors were anxious to be released. Parker also objected to this language of Judge Elliot: "You are advised that the court is of the opinion that the facts in this case overwhelmingly justify you in the conclusion that it was the policy, and therefore the agreement for years of this national organization, to prevent mining of nonunion coal. There is no question in the court's mind but that the strike was ordered to prevent this."

Give the Foreigner Your Hand

We proclaim Americanism as a great gift. Then let us bestow it on the stranger with all the good will we express when we give a Christmas present. Let him know that it is his, from the cordiality of our smile, the heartiness of our handshake and the warmth of our good wishes.

EDITORIALS

May We Show the Warrior a Seat?

EVERYONE is anxious to see the mining men now in the Government forces get back into positions just as good as, if not better than, those they left when they prepared themselves to make the supreme sacrifice and started for camp and the front. Times are perhaps not entirely opportune for men to be looking for new positions, for the energy of production has somewhat spent its force. Still the fewer the places the more diligently they must be sought.

We are willing to help in that search. We have a "Positions Vacant" column in which we shall be willing to run free for four issues the advertisement for a position of any men released from service in the United States Government forces. We desire to know in each instance whether the applicant desires to receive a direct reply or would prefer that it be sent in care of *Coal Age,* to be forwarded without charge. The branch and unit of service from which the advertiser has been released should be given when forwarding copy, which item of information will serve as a credential.

Our International Flag

NO NATION can succeed that does not at times use violence in its defense and force to back up its beliefs. But neither can any nation succeed by force alone. For this reason, we may perhaps find in the future that the principal gain in the Great War was the outcome of our moral and not of our physical forces; and this came largely from the activities of the Red Cross and kindred charitable undertakings, more active in this war than in any other.

The reputation of no nation can rest in security solely on its record for bravery and success in war. A record of liberality is a far safer ground for honor, and it was our happy task to exhibit both bravery and liberality during the advance of our armies under the national banner and the banner of the Red Cross.

In their work the Red Cross officials want the backing of all America. They want a gift of one dollar from every man, woman and child from Carysford Light, in Florida, to the light on Tatoosh Island, in Washington. The hope and expectation is that the people individually will put themselves behind the great altruistic endeavor of the Red Cross, not alone that the noble purposes of that organization may be financially supported, but so that in all the work the officials do they may be able to declare that it is the whole manhood, womanhood and childhood of America that furnishes their work with its support.

A league of nations has once again been urged upon the public, as it has been time without number in the history of the world. It will involve for all nations a lot of self-denial. At heart we are all Tories and believe that an autocracy, with ourselves as the autocrats, would be better than any democracy that could be imagined. Therefore we, as nations, one and all approach any proposition for an international league with reservations. We reserve this and that, each for ourselves, as being something not safely left to the judgment of a congress of nations, because such a congress could not possibly, we feel, view these private matters of ours as rightly as we can.

But whether we have a league of nations or decide that such a league involves a greater sacrifice than we are willing to make, and more faith than we are possessed of, nevertheless we can, as individuals, break through the hard shell of our national environment in the generous work of the Red Cross. The Red Cross is truly international, and for all the earth its flag is an emblem of international sympathy and world-service.

In it is reflected all that is best and noblest in our character, all our benignity, self-sacrifice, humanity, intelligence and comprehension. That being so, membership of the Red Cross by us all, each individually, is a symbolic act of attachment to the best and truest in our international life, is a sign that our hearts are ready for union if our governments are not.

Germs Linger After Influenza Leaves

INFLUENZA is by no means at an end. A recurrence of its attacks is reported almost everywhere. Influenza may be like typhoid fever, which is also a germ disease, in that the germs of it may still be carried by those who have suffered from the disease long after they have become immune to its toxic effects. Such people should be extremely careful not to infect others. They should never relax any of those precautions which they felt it was necessary to take to protect others when still suffering from the disease. While it may not be true that the formerly afflicted continue to be a danger to the community, the probability is so great that no chances should be taken. Sanitary isolation is not so difficult or expensive that it cannot be persistently adhered to. Patients who are getting well seem utterly disregardless of the fact that while the germs have lost the power to hurt their first host, they may be as able and as active as ever to invade the organism of another host.

Four-minute men are needed urgently for service in stemming the disease. It should not be considered a mistake to call meetings for health propaganda, at least in the open air. At these meetings the life story of a germ might be told, tracing its passage by means of a towel, a cup, a wash bowl, a pillow slip, a cough or a

sneeze, from one victim to another. Sanitation is somewhat laborious and expensive; able and persevering must the four-minute man be who will induce the workman and his good wife to take the needed precautions. If a miracle-working drug which would defend the taker against influenza cost $100 a person, it might be possible to get everyone to buy it; but the admonition "Wash and be clean" is a less pleasing, and a bothersome way of meeting the difficulty, and it is hard to make the public accept it. It is not easy to convince the average person that almost none of us are free of faults which should, from a physiological standpoint, be labelled grossly uncleanly.

What the Public Does Not Know

WE WONDER, with justice, how naturalized foreigners who do not know the first thing about civics, the constitution, history and what not can vote with intelligence on American governmental policy. But when we think how little people in general know about coal, we are just as much justified in wondering why they consider themselves able and ready to regulate its production, distribution and consumption.

There is the Mayor of New York, for instance. Discovering a pile of buckwheat anthracite, he said he was going to see why the "poor" could not burn it. (Why impose it on the poor?) There, too, was the man who argued boldly that no matter what might be said, anthracite small sizes were in great demand in Baltimore. This same man, on being questioned as to the way in which he knew there was a shortage of small sizes, said that he had ordered coal for his own household furnace and had only received half of what he ordered. He finally explained that he wanted nut coal, and that in his belief nut was a "small size."

So it goes all along the line. The public doesn't know anything about coal. It can't understand that small sizes are what it calls "dust," and even "dirt." It does not understand that small sizes are always part of the product of every mine. There are those that believe there are chestnut mines and egg mines, and that when there isn't enough chestnut it is because the cruel coal baron has the chestnut mine locked up and hasped, and has wedged a rance securely up against the door.

The consumer does not know that one quarter of all the anthracite mined is buckwheat coal, of varying degrees of fineness; that another 10 per cent. is pea, for which the consumer is even now only just acquiring a tolerance. Thus as much as 35 per cent. of the fresh-mined coal the domestic consumer really doesn't want. But it has to be mined. However, by diligent coaxing, the operator gets most of his 35 per cent. on the market at a cut rate. Of the other 65 per cent., 25 per cent. is nut, 20 per cent. is stove, 15 per cent. is egg and the rest "broken."

Every now and again some tribune of the people hears of a deposit of coal containing some millions of tons. This coal is already being mined at the utmost speed possible under the conditions obtaining, but the tribune of the people believes that if he were down there he could put those millions of tons aboard cars in a week at some impossibly low price. If the public understood the true conditions he would be laughed at. The people would not be so gullible; there would not be so many bewildered misleaders to guide them headlong to the ditch.

Much has been learned during the recent shortage about the conditions environing coal production, and the public is beginning to understand also the possibilities of utilizing domestically other fuels than large size anthracite. But there is much work remaining to be done. Some of us forget that there are hosts of people in the Eastern cities who don't believe that bituminous coal can be, and is, used for domestic purposes. Misconceptions of the plainest facts about coal are common, but one finds it hard to scheme a way to enlighten the voting public. If their only lack were in their knowledge of coal it would be easy, but there are so many matters in which they need new light and so many industries of the nature of which they have only the faintest of inklings, that the work of their enlightenment seems endless.

However, we shall have to rely on their judgment such as it is. They decide the laws and regulate the national policy. If there is a way of making them understand and qualify for the job that they must perform, that way is surely worth the finding.

Keep Iron and Wood Out of Coal

IMPURITIES in coal which reduce its efficiency are trying enough, but other impurities like hardwood caps and pieces of iron (pit-car links, pins and swivel couplings) not only dilute the coal and so give it less thermal efficiency than it should have but do damage to automatic stokers. We have been asked by a member of the Fuel Conservation Division of the Railroad Administration to draw attention to this difficulty.

We can the more readily do it because the operator is partly to blame and we have in these columns an unequal opportunity to appeal to him. Where pit cars are leaky, the miner can do nothing else than use a cap piece to correct the trouble. Poor doors and broken bottoms sometimes need a temporary repair. The cap is handy and is used for that purpose.

As for the car links, pins and swivel couplings, they are not shipped from malice aforethought. They are thrown on the car by the driver merely for use when needed. Drivers, like other men, sometimes forget to pick up what they lay down, and the iron then goes into the car with the coal.

Then, again, the railroad itself is sometimes to blame. Its cars, like those of the operator, at times need patching and the cap piece is used for that purpose, rightly so it seems to us. However, no one has worried much about these matters hitherto because a piece of wood or of iron did little harm with hand-stoking. As times have changed, it is necessary to call attention to the importance of avoiding shipment to market of material in the coal which in the use of that fuel may damage machinery. The loaders beneath the tipple should always be instructed to clean out the railroad cars before loading them. When, however, several inches of frozen material are found in a car, it is often a question to determine what should be done.

DISCUSSION BY READERS

Zoning System of Coal Shipments

Letter No. 1—I have been greatly interested in the numerous references made in *Coal Age*, regarding the zoning system adopted by the Fuel Administration regulating the shipment of coal. It is unnecessary to state that the zoning system, which was made necessary during the war crisis, has since become a matter of deep concern to coal operators in certain districts. Our own experience in this regard is by no means exceptional.

Allow me to say that our company is operating a mine located at Bream, W. Va., and shipping on the Coal & Coke Ry., at that point. Since the war started, we have spent more than $50,000 for modern equipment, which enabled us to increase our output as urged by the Government to help win the war.

The practical effect of the zoning system is to limit the sale and shipment of coal outside of the limits of the zone in which a particular mine is situated. Since Saturday, Oct. 23, it has been our misfortune to have no orders in the zone prescribed for shipment from our mine; and, as a result, the mine has been forced to lie idle for more than a week.

Zoning System Restricts Trade

The fact is that the states embraced in our zone of shipment are oversupplied with coal, while other states where there is a large demand for West Virginia coal can get none of our product despite their frantic efforts to do so. It happens that West Virginia coal is suited for their particular purpose better than the grade of coal that they have been and still are obliged to use because it is mined in the zone in which they are located.

Our sales agents inform us that they have orders for coal in Indiana and the East, where they could place all our present and future output, as quickly as mined. In common with all the coal operators in West Virginia, we have considered it a patriotic duty to conform in every respect and to comply cheerfully with the rules of the Fuel Administration made to better the movement of coal during the war.

Is it, now, too much to ask for the powerful protection of the same Fuel Administration during the present period of readjustment? Do not the principles of readjustment of economic conditions, following the war, call for the unrestricted shipment of coal to points where operators have urgent orders for their product?

It is only justice to state, here, that coal operators are losing, and will continue to lose, large amounts of money if the restrictions of the zoning system are to continue in force while the demand for coal has shrunk, in some zones or districts, to such an extent that our mines are idle. At the same time, the country loses the output of these mines and the coal industry is sadly handicapped because of the inability of operators to ship their output where it is needed.

Our operators, relying on the impartial judgment of the Administration, and their spirit of justice, firmly believe that permission will shortly be granted them to move their coal to points in other zones where they have urgent orders waiting to be filled.

It is for the purpose of inviting a free discussion, in the columns of *Coal Age*, that I have written this letter, hoping that such a discussion will serve to draw the attention of the Fuel Administration to existing conditions and the need of reconstruction in respect to the shipment of coal from mines, which is a fact that is absolutely necessary to maintain the healthful growth of the coal industry in the country.

Ernest B. De Ligny, Pres.,
New York City. Empire Coal Mines Co.

Air-Cylinder Lubrication

Letter No. 2—In looking over some of the recent issues of *Coal Age*, my attention was attracted to the inquiry of an engineer who had experienced trouble in the lubrication of the air cylinder of his compressor, and asked to be informed in regard to the best lubricant to use for that purpose. I have had some experience in the lubrication of cylinders and can appreciate the correspondent's situation fully.

Although everything stated in the reply to this inquiry is quite true, I was surprised to find that the writer omitted to mention one of the best air-compressor lubricants manufactured or used. I refer to flake graphite, which has no equal as a lubricant not only in air-compression practice, but likewise for steam engines, gas engines, journals, valves, and, in fact, wherever a lubricant of superior quality is required.

Lubricating Qualities of Flake Graphite

Flake graphite possesses the peculiar properties not found to the same degree in other lubricants. For example, its structure is such that it fills up or overlays the roughnesses of metallic bearing surfaces. As is well known, graphite has a strong tendency to attach itself to a metal surface and quickly imparts to it a superficial glaze that almost eliminates friction.

Again, used as a lubricant, graphite is not only more enduring than oil, but possesses the important feature of withstanding high degrees of heat. It is this feature particularly that adapts it to the lubrication of air-compressor and gas-engine cylinders, where the heat is sufficient to volatilize or carbonize oil and render it useless as a lubricant under such conditions.

Everyone who is familiar with the operation of air compressors or gas engines freely admits that oil has many disadvantages that render its use inefficient and often harmful. The use of graphite for the purposes named would have become universal long since had it not been for the difficulty encountered in introducing the graphite into the engine cylinder.

That difficulty, however, is more imaginary than real. Special devices have since been made for automatically feeding flake graphite into cylinders and on all bearing surfaces that must be lubricated. One of these devices is known as the Winans Dry Graphite Lubricator; another, Johnson Graphite Lubricator. It is claimed for each of these that from 50 to 60 per cent. is saved in the cost of lubrication, by the use of graphite instead of oil.

In my own practice, I have been using Dixon's Ticonderoga Flake Graphite for the lubrication of air-compressor and gas-engine cylinders, as well as on other moving parts, in all classes of mechanical equipment. Permit me to name a few of the advantages I have found that graphite possesses over oil when used as a lubricant. They are as follows:

Graphite, in lubrication, (1) is unaffected by high temperatures; (2) cannot be carbonized or ignited; (3) cannot give off explosive vapors; (4) does not clog discharge valves; (5) will not accumulate dust or grit; (6) enables a large saving in cost of lubrication; (7) avoids danger of explosion in air-compression practice.

Last, but not least, I have found that the use of graphite in cylinders improves the fit of the piston, while at the same time reducing friction, making repairs less frequent and saving trouble and expense.

Paterson, N. J. ANOTHER ENGINEER.

Efficiency in Firebossing

Letter No. 1—In reading some of the recent articles that have appeared in *Coal Age*, where references have been made to the treatment of firebosses, I have wondered whether any of the mining men who have struggled from the bottom to the top, via the fireboss route, have experienced the same feeling that I have when they see such statements as sometimes appear in print.

It is hard to find words that rightly express my sentiments at the time of reading some of the fireboss' duties in different states. The words "from the sublime to the ridiculous" flit through my mind, although they do not fully convey the impression made. My feelings are similar to those a man experiences when reading a good cartoon in *Life* or *Punch*. First comes the pleasure the cartoon excites; then follows contempt mingled with sadness when one reflects on the true situation.

Underrating the Status of the Fireboss

Undoubtedly, each of the coal-mining states have different conditions with which the fireboss must contend, and his status will naturally vary with these conditions. While, in some states, he is rightly regarded as a mine official and treated as such, in other states he is a combination of a mine examiner, coal digger, timberman, or trackman, as the case may require.

Although my experience is varied, having been gained by travel and work in many mining countries, it would be presumption on my part to comment on the practice in any one state, without knowing the exact conditions in that district and state. However, when I read of a mine foreman putting his fireboss to work digging coal, laying track, or timbering haulage roads, it is evident to my mind that the foreman is off the track, all wheels.

As in other trades, success in mining is primarily due to organization and, to obtain this, it is necessary to have efficient officials and mutual confidence. Let me ask, Is a foreman who puts his fireboss to work to dig coal, or to lay track or switches, proceeding in a manner to develop the highest efficiency in the particular work that fireboss must do each day? Is the foreman doing his duty to the company or to the fireboss? Does he not, rather, undermine confidence and destroy ambition?

To my mind, a man who spends two-thirds of his time digging coal would be a poor man to put in charge when the emergency arises calling for higher duties. My claim is, then, every mine official must perform his work conscientiously. The foreman should teach the man under him to take his place and act for him in his absence, while at the same time the foreman should prepare himself for assuming higher duties when the opportunity offers. It is a mistake for a foreman to run a mine in such a manner that the loss of any one man would prove a severe blow to the efficient operation of the mine.

Frequently, the fear of being supplanted in his position will keep a foreman from training men under him so that they will be able to take his place. When the fireboss, in the early days, went about the mine burning out the gas before permitting the miners to proceed to their work, there was little cause for jealousy and few men were ambitious to assume the duties of that position. Today, however, there should be every incentive to ambition and mine officials should strive continually to foster that ambition in the men working under them. No foreman should attempt to run a difficult and dangerous mine with the organization of the "mine-examiner-coal-digger principle." Such an attempt will only prove a failure. A poor foreman with a good fireboss under him will often pull through; but a good foreman with poor firebosses under him stands a poor chance for success.

Dangers and Responsibilities of the Position

The fireboss should be, and is, in many mines and in many respects, as important as the foreman. It is the fireboss whose duties call him to enter the stygian darkness of the mine at an ungodly hour and face unseen dangers with every sense alert. It is the fireboss who is responsible for reporting what places in the mine are safe for work and in what places dangers exist. Where everything is in good shape, the work of firebossing is performed without unusual effort; but more often difficulties are encountered, such as overflowing sumps, roof caves, accumulations of gas owing to the ventilation being poor or the air current short-circuited by the setting open of a door. It is then that the fireboss emerges from the mine, at the last moment, wet through and "all in."

In addition to answering questions regarding the general safety of the mine, the fireboss must often give accurate answers to questions as to the number of cars, empty and loaded, on certain landings, the quantity of water in certain sumps, the quantity of timber on hand or needed in the workings, and the amount of loose coal that is ready to be loaded, etc.

Having fulfilled these duties in compliance with the law, his report being signed, it happens too often that the remainder of the day must be spent "carrying bricks," or, in other words, doing odd jobs about the mine, according to the custom prevailing in that district

or state. Instead of continuing to examine each working place and giving needed instructions to men regarding their safety, the fireboss is too often made responsible for getting out the coal. He soon learns that, in order to be classed as a good man, he must have the name of a hustler. He is taught that promotion comes to the man who can get out the coal.

Viewed from almost any angle, it must be admitted that firebossing, in many coal-mining states, offers little inducement to the best trained men, and this, again, acts as a positive hindrance to securing good foremen, since it is the faithful fireboss who is acquainted with the conditions throughout the mine and who is better fitted for the work of foreman than many men who now hold that position, provided the fireboss possesses those qualifications that fit him to take charge of men. Let me urge, in closing, that the fireboss be regarded as a mine official, put on the salary list and treated by the mine foreman as his assistant which will not only establish confidence but stimulate ambition and increase the efficiency and safety of the mine.

Chicaloon, Alaska. F. G. J.

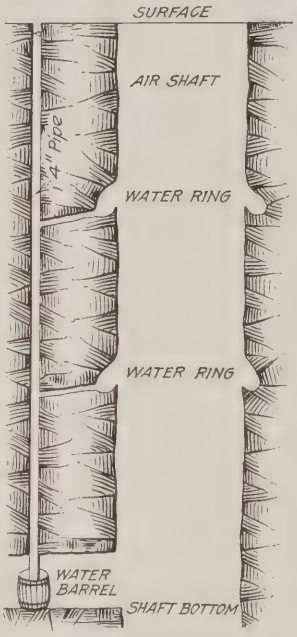
Freezing of Shaft in Winter

Letter No. 1—I was interested in the inquiry regarding the freezing of shafts in winter and want to ask why it would not be possible to overcome this trouble, which occurs so frequently in coal mining, by installing a hot air chamber near the top of the shaft. I have never seen this tried, but it would seem to me that such a scheme could not fail to warm the air sufficiently to prevent the shaft from freezing.

To explain more fully my idea, I would say an oven should be built at one side and near the top of the shaft. The idea is to install a furnace or heating system similar to that used for heating homes in winter. A 12-in. pipe could be used to conduct the hot air from the furnace, or hot air chamber, into the shaft.

It is my belief that to reverse the fan in order to prevent the freezing of a shaft would conflict with the requirements of the mining law, in some states. A hot air system such as I have mentioned seems to me better than the use of steam coils for heating the air. I shall watch this discussion with interest.

———, Penn. Evan Jarvis.



Letter No. 2—Looking through a recent issue of *Coal Age*, I noticed an inquiry in regard to the best method of preventing the freezing of a mine shaft in winter. As I had been up against this same problem, several years ago, I was naturally interested in reading the inquiry and the reply thereto.

The plan that we adopted was so successful that I have often wondered that many of our smart engineers and mining men have not tumbled to the same idea. When I think of the simple way in which we overcame the difficulty, the correspondent's suggestion of putting in steam coils at the shaft to heat the intake air seems funny to me; and the further suggestion, offered in the reply to this inquiry, of impregnating the water draining into the shaft with salt does not appeal to me.

In explanation of the method we adopted, let me say that I saw the idea first tried out at a mine where I worked some years ago. At that mine, the air shaft was located at the extreme end of the field; and, as the fan was exhausting, the air was drawn into the mine through this air shaft. The shaft was very wet and, naturally, froze up in cold weather and gave much trouble. It often happened that the air current was completely shut off by the ice, which would close the shaft tight.

Draining the Shaft by Means of Water Rings and a Borehole

Under the conditions described, it is clear that it would be impracticable to put in steam coils to heat the air. Also it would be a difficult job to impregnate the water with salt to prevent it from freezing in the shaft. The method we adopted is shown in the accompanying figure.

DRAINING A WET SHAFT

A hole was drilled about 6 ft. outside of the shaft curbing, and a 4-in. pipe inserted in the hole. Water-rings were put in at points in the shaft where the water entered. These rings were then tapped into the drillhole so that the water drained to the bottom of the shaft. In order to trap the air and prevent its entering the pipe, the latter discharged into a barrel, the end of the pipe being submerged in the barrel, as shown in the figure.

It was important to keep the end of the pipe submerged in the sump or water barrel at the bottom of the shaft. If this is not done the air entering the pipe from below will cool the pipe and cause trouble. This method has been tried in a number of wet shafts and has proved successful in every case.

Smock, Penn. Mine Foreman.

Letter No. 3—Referring to the question of preventing the freezing of a shaft in winter, as suggested in the inquiry that appeared in *Coal Age*, Nov. 28, p. 1004, kindly permit me to give my experience in this regard.

For the past 15 years I have used the exhaust steam from the fan, for this purpose. Putting a valve in the exhaust line and extending two joints of pipe down the shaft made it possible to use part or all of the exhaust steam, according to the condition of the shaft. The plan proved very successful. Previously we had tried the method of reversing the fan at night, but this caused considerable confusion and expense, besides freezing up the hoisting shaft and cages.

Use of Exhaust Steam Removes Ice Trouble

At one mine, our downcast shaft was partitioned off to provide for a hoistway for lowering men and supplies into the mine. In that case, although there was a water ring surrounding the shaft, we had no end of trouble and delay, both in the airshaft and the hoistway. The accumulation of ice threw the cages and the coun-

terweights out of the guides, or bound them fast so as to prevent their operation.

The ventilating fan at this mine was a blower, producing 100,000 cu. ft. of air per min. When the exhaust steam from this fan was turned into the shaft, the ice disappeared and we had no further trouble. The steam, moreover, increased the humidity of the air, which was a decided advantage, considering the dry and dusty condition of the mine. Since that time, we have used the same method every winter and have had no trouble. Whenever I have seen men engaged in cutting ice in shafts, I have advised them to use the same method wherever exhaust steam from the fan or pump was available.

Experience Relates to Shallow Shafts

It may be well to state, however, that my experience in the use of exhaust steam for preventing the formation of ice in shafts is confined to comparatively shallow openings, the shafts being 200 and 350 ft. in depth, respectively. We are using the same method at present and utilizing, in addition, a part of the exhaust steam from the pump located at the bottom of the hoisting shaft.

It is my belief that this method can be depended upon to keep a shaft free from ice and produce no ill-effects. I will say that, as the mine advances and the first entries are worked out, we carry part of this steam on the day shift, as it is quickly absorbed in the air current and does not extend to any working place. I trust that others may find this plan of value, and that it will help them to overcome what is always a serious trouble in coal mining. Superintendent.

Athens, Ohio.

Portable Coal Loaders

Letter No. 1—Having given much study to the question of loading coal by means of a mechanical shoveler, I was naturally interested in the inquiry that appeared in *Coal Age*, Nov. 21, p. 961, in which an operator, at Rugby, Colo., asked for information regarding portable machines for loading coal at the working face. I am glad to give him a little of my own experience along this line.

During the past 15 months, we have had a Myers-Whaley coal shoveler and loader at work in our mines. This is a No. 4 machine and has been used for excavating bottom coal after shooting. It has given excellent satisfaction. It is guaranteed to shovel and load, dependably, 40 tons of coal per hour, or 1 ton per minute of heavier material.

More recently, we have been running into thinner coal, which makes it desirable to trade off our No. 4 for a No. 3 machine that would work better in the low coal we are now mining. The No. 4 machine works well in a 6- to 8-ft. seam. I have no hesitancy in saying that, in such a seam, with good tracks, good motive power and plenty of loose coal at hand, the machine will surely load its guaranteed capacity.

For his information, let me say to "Operator" that he can see these machines at work at some of the mines in Utah, where they are in regular and successful operation. My belief, based on experience, is that wherever this machine is installed and given personal attention, it cannot fail to prove an unqualified success. The fact that the manufacturers are behind on their orders, also bears out that statement. We have used our No. 4 machine on a 42-in. gage track, operating with direct current at 250 volts. C. H. Thompson, Vice-Pres.,

Darbyville, Vt. Darby Coal Mining Co.

Constructive Practice in Mining

Letter No. 1—Before taking up my work on the Fuel Administration Board I was engaged in mine-welfare work, which has caused me to be intensely interested in the recent letters of *Coal Age* readers discussing the safety of miners; the elimination of the alcohol curse; the Americanization of foreigners; and the increase of coal production by the use of modern methods and machines. Too much cannot be said on these subjects, for they are the most essential problems in the great coal industry today. Their discussion is constructive.

One of the writers very properly referred to the shortcomings of the miner. It would be wrong, however, to infer that the careless action of employees, in any way, excuses the employer from taking every possible precaution for the safety of his men. Unfortunately, the examples of the carelessness of mine workers are only too true, which any man familiar with mining conditions knows by experience. But the very nature of the foolish acts of some miners points to the necessity for double care and thought on the part of every conscientious mine operator and, likewise, every responsible man who represents him.

Training Men for Safety

Foolish acts of workers indicate that the men who perform them are not men but boys, mentally, if not in years. They cannot be treated, therefore, in the same manner as men who do their share to make mining a safe occupation, but must be handled as men regard boys. The man foresees dangers that beset the path of the boy and strives to remove the danger to the best of his ability. The same preventative action on the part of the operator requires constant vigilance, constructive thinking and an exact knowledge of every phase of the work.

The miner spends at least a third of every day in the mine and the man who is to make the mine safe for him cannot hope to do so, effectively, unless he also spends much of his time in the mine. Even a conscientious miner is prone to feel that, while he is in the mine, his safety is up to the boss. He knows the law requires the protection of employees, but he seldom realizes that it is his duty to coöperate in carrying out that provision of the law, and he must have safety thrust upon him. Adequate ventilation, proper timbering and the carefully regulated use of lights are safety fundamentals so important that they are laws.

The ever-present problem of mine safety has two important aspects. The operator must not only strive to make his men safe men, who will obey the rules and take necessary precautions, but he must also keep them safe, by adopting every possible form of safety device and by lessening every dangerous condition that exists in his mine. The more successful he is in making his

men safe men, the less attention he will have to give to keeping them safe; for careful men will keep themselves safe in spite of dangers. They will, also, assist by reporting dangers and making suggestions for their removal. To make men safe men, they must be educated and given a sense of responsibility, which means the personal development of each man.

Protecting the Homes and Making Life Attractive

Many mining companies realize that good housing conditions is an important factor in raising the standard of employees. Houses should be so built that it will be possible for those who live in them to make them into homes. A man with a real home will give his employer far better service than when compelled to live under disagreeable conditions. Houses should be sanitary, warm and kept in good repair. They should be as attractive as possible. To make a house attractive does not require extra money for material and labor, but only requires extra thought in making the plans.

The company doctor, if possible, should have duties beyond the bare attendance of the sick and injured. His work should be largely educational and along the lines of prevention rather than curative. We are relying, for the operation of our mines, on a large percentage of foreign-born men with little or no idea regarding sanitation and health. A doctor of the broad human type can do much to enlighten the minds of these people and keep them healthy and in good working condition. Another means in the improvement of the home conditions of miners is through the school. Children's minds are fresh and unhampered by custom. They are quicker to catch the new ideas and are able to introduce them into their homes most effectually.

Alcohol is without doubt the supreme curse of every mining center, but the curse can only be removed by country-wide prohibition. State prohibition is calculated to upset labor conditions, but absolute dryness throughout the country would be of incalculable advantage to the mining industry as well as to every human enterprise. Until such prohibition comes, however, the evil can be mitigated by careful regulation of the sale of alcohol and by providing suitable counter attractions. Unfortunately these are few; but some good work can be done with the younger generation who have not as yet fallen victims to the curse. Company clubs and schools, outdoor sports and games, good moving pictures, and the encouragement of religious organizations are effectual means of combating the saloon.

Safeguarding the Work in the Mine

Turning again to the actual work in the mine, greater safety in blasting coal and rock is assured by providing the proper explosives and allowing only carefully trained men to use them. There are laws that limit the amount of explosives that may be carried into the mine by each man. Strict adherence to these laws and the giving out of explosives to authorized men only should be the standard practice among all mine officials who really care to make their mines safe. The daily use of explosives makes men forgetful of their power and unstable nature. It is therefore important to keep fresh in the minds of the men the fact that they are working with a strong but treacherous ally.

Many men are yearly injured and killed by the many mechanical devices that are so valuable in increasing production. These devices can be made safe, however, without interfering with their productiveness. The use of modern types of mine cars makes far more efficient haulage conditions. Most coupler accidents causing the loss of fingers can be avoided by the use of modern couplers that have been found useful in railroad work, and adopted in many of our best mines.

Cars equipped with roller bearings, especially in mines where they are pushed by hand, have a distinct safety value in cutting down the danger of strained backs, which are frequently caused when men have to push the old type of cars. Moreover, the latter is a menace to the men, because the old car spreads oil along the track, making it unsafe to walk and adding to the possibility of fire.

The installation of positive signal devices will guard against chance collisions. Here, again, education of the men must supplement the mechanical device in order that they will not disregard the signals. Such signals belong wherever there is any possibility of locomotives or cars running into each other. Continuously sounding signals on moving trips avoid running men down.

Dangers in Mines Electrically Equipped

Too much cannot be said relative to safeguarding mine workers against contact with live wires wherever the electric current is used in mines. A large majority of miners are ignorant of the laws of electricity and although they may have a healthy fear of its effects their very ignorance lays them open to its dangers. Education must always supplement protective devices. Automatic cut-out switches insure the harmlessness of the trolley in any working district during the absence of the locomotive. The motorman may forget to make the trolley safe behind him, but the trolley wheel performs that function for him. Careful insulation of cables to coal cutters and coal loaders is necessary, and these cables should be frequently inspected to detect any serious abrasions of the insulation, which is likely to occur due to the rough handling that the cables receive.

By the use of a good system of communication between the surface and the various internal parts of the mine, much guesswork is eliminated, which is always a source of danger. Many accidents occur to men working around a shaft bottom and to men while being hoisted to the surface. There are practical protective devices to keep men working at the shaft bottom from being struck by falling coal. Installing such devices makes that part of mining equipment a much safer proposition. With the coal at the tipple and the mining operation practically complete, easy moving cars and good car unloaders do their share in minimizing tipple accidents.

Warning signs, in as many languages as there are nationalities working in the mine, are necessary wherever there is danger. The use of steel signs will prevent alterations and destruction of these warnings. Mining will never be an altogether safe operation, but its degree of safety can be brought much higher by constructive, conscientious effort on the part of the mine operator. Many mine operators are willing to make this effort for the good of humanity alone; but even those who are not should be as much interested, for it means increased production at a less cost per ton.

Washington, D. C. Maverette Ashley.

INQUIRIES OF GENERAL INTEREST

Winding Armatures

Would it be possible, through the medium of the *Coal Age* columns, to ask readers to discuss the different methods of winding armatures, explaining the tools used for that purpose and describing the particular adaptation of the methods employed and the advantages resulting therefrom. Permit me to say that I am an armature winder by trade, myself, and have found that different types of machines require different methods of winding.

It has occurred to me that a practical discussion along these lines might be of interest to all who are engaged in coal-mining practice. I have found much helpful information in reading many of the discussions in *Coal Age*, and feel that, while the subject of winding armatures is a wide one, many points may be brought out that will help to simplify the work.

Molus, Ky. GEORGE W. RAMSEY.

A volume could be written on the subject suggested by this correspondent, and a discussion of the different methods employed in winding armatures would necessitate much detail in the way of illustration and, at the same time, be apt to cover ground that is already fully covered in textbooks treating the subject. Hence, it does not appear that there would be any great advantage in a discussion of the methods of winding armatures. *Coal Age* will be glad, however, to receive the suggestions of readers bearing on the subject, with particular reference to explaining kinks or points of practical interest that may prove helpful in expediting the work of winding and simplifying what is difficult in the process.

Wire-Rope Formulas

Among the examination questions answered in *Coal Age*, Oct. 31, p. 838, is one giving the method of calculating the breaking strain and safe working load of a $1\frac{3}{8}$-in. steel hoisting rope. I want to ask if the same formula will answer for calculating the breaking strain of different ropes; as, for example, ropes of Swede iron, cast steel, extra cast steel and plow steel. Also, how do haulage ropes differ, in this respect, from hoisting ropes, which the answer to the question referred to states is a 6-strand, 19-wire rope. Kindly give the formulas used for calculating the strength of the different wire ropes used in mining practice.

Witt, Ill. JOHN H. PLANT.

The formulas for calculating the strength of all kinds of wire rope are of the same general character as that given in the answer to the question to which this correspondent has referred. The formulas relating to the different kinds of rope differ only in the constants employed.

Hoisting ropes differ from haulage ropes in the requirement that they must be more pliable to withstand the severe jerks and sharp bends to which they are subjected, in the daily practice of hoisting in shafts. In American practice, both hoisting and haulage ropes consist of 6 strands. Each strand of a hoisting rope, however, has 19 wires, while a single strand of a haulage rope is made of 7 wires.

The 19 wires forming a strand in a hoisting rope are much smaller and therefore more pliable than the 7 wires that make up a strand of a haulage rope. The larger wires of the haulage rope are better able to withstand the abrasion to which such ropes are subjected in mine haulage. In conclusion, therefore, hoisting ropes are adapted to withstand bending, while haulage ropes are fitted to withstand abrasion.

The following formulas are based on the tables giving the breaking strength of different sizes of the four kinds of wire ropes manufactured for mining use. These tables were published by manufacturers of wire rope in this country. The constant in each formula is the breaking strain of a 1-in. rope of the material stated.

In hoisting practice, today, cast steel, or extra crucible cast steel ropes are chiefly employed. The breaking strain of a 1-in. cast steel, 6-strand, 19-wire hoisting rope, as taken from the tables mentioned, is 34 tons, while that of a similar, extra or crucible steel rope is 39 tons. Following are the formulas giving the breaking strain, in short tons (2000 lb.), of each kind of rope employed for hoisting and for haulage purposes:

	Hoisting Ropes 6-Strand 19-Wire	Haulage Ropes 6-Strand 7-Wire
Swede iron	$S = 17d^2$	$S = 16d^2$
Cast steel	$S = 34d^2$	$S = 32d^2$
Extra cast steel	$S = 39d^2$	$S = 37d^2$
Plow steel	$S = 44d^2$	$S = 42d^2$

In these formulas, S equals the breaking strain of the rope, expressed in short tons (2000 lb.); and d equals the diameter of the rope, expressed in inches. In ordinary mining practice, in shafts not exceeding, say, 300 yd. in depth, the safe working load of a hoisting rope is commonly taken as $\frac{1}{8}$ of the breaking strain of the rope. In deeper shafts, the safe working load may vary from $\frac{1}{8}$ to $\frac{1}{10}$, depending on the depth of the shaft and the style of equipment.

Elements in Mine Ventilation

Assuming a large mine capable of producing 3000 tons of coal a day, kindly say what are the three elements essential to its efficient ventilation.

Springfield, Ill. STUDENT.

The three elements most essential to efficient ventilation are: A mine fan of sufficient capacity to produce the required air volume; a proper distribution of the air current in the mine; and, third, well-built stoppings, doors and overcasts that will prevent the leakage of air through them.

EXAMINATION QUESTIONS

Hoisting Engineers' Examination. Springfield, Ill., 1918

(*Selected Questions*)

Ques.—How would you test a steam boiler to ascertain its safety?

Ans.—To insure the safety of steam boilers, they should be inspected regularly and kept free of all accumulations of sediment. The condition of all joints, rivets and stays should be carefully observed. The only safe method or test to apply to a steam boiler to determine the pressure it can safely carry is the hydraulic test, which consists in filling the boiler full of water under pressure and noting any leaky joints.

Ques.—What is the available power of a pair of hoisting engines, with 24-in. cylinders, 5-ft. stroke, when making 40 r.p.m., the gages on the boiler indicating a pressure of 75 lb.?

Ans.—With a boiler pressure of 75 lb. gage, the mean effective pressure in the cylinder of an ordinary slide-valve engine, cutting off at, say ⅔ stroke, may be taken as 60 lb. per sq.in. The sectional area of a 24-in. cylinder is $0.7854 \times 24^2 = 452.4$ sq.in., and the total pressure on one piston of the engine is, then, $60 \times 452.4 = 27{,}144$ lb. With a 5-ft. stroke, an engine making 40 r.p.m. has a piston speed of $2 \times 5 \times 40 = 400$ ft. per min. Finally, assuming the efficiency of the engine as 85 per cent., the available horsepower, under the assumed conditions, is

$$H = \frac{0.85\ (27{,}144 \times 400)}{33{,}000} = 280\ hp.$$

In hoisting practice, it is customary to estimate the power of a duplex engine on the basis of a single cylinder, as one cylinder is carrying the full load when the other cylinder is on dead center.

Ques.—What kind of engine would you prefer for hoisting at coal mines?

Ans.—Because of its simplicity of construction, the ordinary slide-valve engine is generally preferred for hoisting, in coal-mining practice, except where a large power plant is installed and the hoisting shaft is deep, requiring a larger engine, and greater efficiency is desired in its operation. In that case, a Corliss engine may be preferred.

Ques.—The piston speed of an engine is 540 ft. per min., the number of revolutions per minute is 150; what is the length of stroke?

Ans.—Since an engine makes two strokes in each revolution, the number of strokes per minute, in this case, is $2 \times 150 = 300$ strokes. The piston speed being 540 ft. per min., the length of stroke is $540 \div 300 = 1.8$ ft., or $1.8 \times 12 = 21.6$ in.

Ques.—How would you fasten a rope on a drum?

Ans.—Before attaching the end of the rope to the winding drum, the former should be passed at least twice around the drum. The end of the rope should then be passed down through a hole bored in the lagging of the drum, and made secure to the drum shaft, by being passed around it and then fastened by a clevis binding the end of the rope to itself. Care must be taken to make no sharp bends in the rope. Two spare coils are required to be kept on the drum as a precaution against overwinding and to provide sufficient length for recapping the rope, at frequent intervals, where it is attached to the cage.

Ques.—How would you open and close the valve to start and stop an engine? Give reasons for your answer.

Ans.—The valve controlling the supply of steam to an engine should be opened and closed gradually, in order to avoid any undue strain on the engine, owing to the inertia of its moving parts.

Ques.—We have a tank full of water, in the morning, when we commence work. We have no more water in sight; the tank is a circular tank 14 ft. in diameter and 20 ft. deep. How long will we be able to run using 1200 hp. per hour.?

Ans.—Estimating a single horsepower as 34½ units of evaporation, which means the evaporation of 34½ lb. of water per hour, from and at 212 deg. F., the weight of water required in this case would be $1200 \times 34\frac{1}{2} = 41{,}400$ lb. per hour. The cubic contents of this tank is $20(0.7854 \times 14^2) = 3078$ cu.ft. Taking the weight of water as 62.5 lb. per cu.ft., the time required to empty this tank under the assumed conditions would be $(3078 \times 62.5) \div 41{,}400 = 4.64$ hr.; or, say 4 hours 38 minutes.

Ques.—If a boiler generates steam at 85 lb. pressure, what percentage may be gained by heating the feedwater, originally at 65 deg. F., by means of a feedwater heater to 200 deg. F.?

Ans.—Using Marks & Davis steam tables, the total heat in steam, above 32 deg. F., at 85 lb. gage or 100 lb. absolute pressure is 1186 B.t.u. The total heat in the steam above 65 deg. F. is therefore $1186 + 32 - 65 = 1153$ B.t.u., which is the heat absorbed in generating a pound of steam at 85 lb. gage (sea level), and a feedwater temperature of 65 deg. F. Now, using a feedwater temperature of 200 deg. F. means a saving of $200 - 65 = 135$ B.t.u. per lb. of steam generated. The percentage of saving is, therefore, $(135 \times 100) \div 1153 = 11.7$ per cent.

Ques.—What is meant by the terms, water line, steam space and the heating surface of a boiler?

Ans.—The term "water line" is the normal water level in the boiler. The "steam space" of a boiler is the space occupied by the steam in the boiler, which is the total space above the water line in the boiler, including the steam dome. The "heating surface" of a boiler is the entire exterior surface of the boiler plates that is exposed to the heat and gases of the furnace, and includes also the inner surface of the flues or tubes of the boiler through which the heated gases pass.

COAL AND COKE NEWS

What Happened in November

[The bracketed figures in the text refer to pages in the present volume and should the reader desire further information he can obtain it by reference to the pages indicated.]

Nov. 1—New wage scale in anthracite region comes into effect, having been approved by Dr. Garfield Oct. 31 [789, 829, 867, 908]—Nichol Thompson, Pacific Coast representative of the Fuel Controller of Canada, raises the price of coal in British Columbia 75c. per ton to accord with the wage increase [920]—Benjamin L. Flynn, general superintendent, Logan Mining Co., Logan, W. Va., dies of influenza [921]—The Fuel Administration declares its intention to commence on Nov. 15 its campaign to provide coal for points in the East, including Pennsylvania, New York, New Jersey and the New England states.

Nov. 2—Fuel Administration announces that 19 more coal mines are closed because their product has been improperly prepared [906]—Fuel Administration decides against regulation of opening and closing hours of offices, stores and other mercantile establishments and places of amusement.

Nov. 4—MacBeth Coal Co. begins the shipment of coal from its Rum Creek mine in Logan County, West Virginia [880]—Tipple and boiler house of the Cross Mountain Coal Co., Briceville, Tenn., burned down [921].

Nov. 6—New anthracite price schedule agreed upon [905]—The railroads in the coke region around Uniontown, Penn., being shorthanded owing to the influenza, call on the employees of the coke companies to help move coke cars [905].

Nov. 7—Dr. Garfield requests that the police survey of New York City's fuel resources ordered by Mayor J. F. Hylan be not made [906]—Burton L. French introduces into the House of Representatives a bill providing for reconstruction projects [952].

Nov. 9—New regulations made regarding "lightless nights"—Regulation made that placing coal in householders' bins shall not permit the retail coal dealer to add more than 75c. to the price.

Nov. 10—Fuel Administration announces that hereafter applications for new railroad switches for use of coal mines shall be filed with local railroad officials and not with the Fuel Administration [949]—Fuel Administration announces that New England desires a reduction in its bituminous coal allotment from 30,000,000 tons to 27,300,000 tons [950].

Nov. 11—United War Work Campaign Fund Drive starts [923]—Armistice is signed by Allies and Germany.

Nov. 13—All restrictions on the use of fuel in the production of building materials including brick, cement, lime, hollow tile and lumber are removed.

Nov. 14—Fuel Administration announces that all rules and regulations in force will so remain till the promulgation of the treaty of peace unless revoked by officers of the Administration [949]—Restrictions on clay products and cement set at half those established in the order of Apr. 3 and Aug. 8 respectively [950].

Nov. 15—Fuel Administration decides to restrict the operations which it has set on foot to promote the more efficient use of power at mining plants.

Nov. 16—Fuel Administration announces that its plan to save by zoning 160,000,000 car-miles seems likely to be more than effected [949, 994]—Fuel Administration announces that it will conduct schools of instruction in the cities of Illinois, Indiana and Michigan at which will be explained how bituminous coal can be satisfactorily used as a domestic fuel.

Nov. 17—Fuel Administration rules that smaller sizes of anthracite than pea shall be sold at a price at least 50c. below that established for anthracite of pea size [950].

Nov. 18—Explosion of gas in No. 11 colliery of the Lehigh Coal and Navigation Co., in anthracite region, kills one and injures six men [1007].

Nov. 19—Frank P. Walsh, joint chairman of the National War Labor Board resigns [952]—John P. White, joint director of the Bureau of Labor in the Fuel Administration resigns [995]—Fuel Administration announces that certain parts of its work such as the supervision of anthracite and the maintenance of the zoning system cannot be suspended, at least at the present [993]—Fuel Administration announces that four more mines have been closed down because of the impurity of the coal produced, making 119 in all.

Nov. 20—United States Fuel Administration announces that instructions have been issued to all camps to release anthracite mine workers [993]—"Lightless Nights" are discontinued throughout the country though rulings may still be made by local fuel administrators if in their belief such a regulation is needed.

Nov. 22—Storage limits on bituminous coal are lifted [994].

Nov. 23—The zone restrictions are modified on the Kanawha and Michigan district in the Kanawha, Guyan Valley and Logan districts of the Chesapeake & Ohio, and the Kenova-Thacker districts of the Norfolk & Western, all in West Virginia and the Sandy Valley and Elkhorn districts in Kentucky. Producers are allowed to ship coal to industrial plants in a part of Indiana and for general use in an increased portion of Ohio.

Nov. 25—Arrangements are announced by Fuel Administration under which Pittsburgh consumers are allowed to store their winter's fuel [1039].

Nov. 26—Fuel Administration speeds up the "Burn Wood" campaign.

Nov. 28—Submarine attacks having ceased, coal from two pools is to be permitted to be sold for bunkering purposes. The coal from these pools makes a telltale smoke which in war would have aided the enemy to discover the presence of the vessels using it—Avondale washery of Delaware, Lackawanna & Western R. R., Coal Department, burns down [1052]—Evan D. John, director of the Illinois Department of Mines and Minerals, dies after an illness of five weeks [1052].

Nov. 30—Dr. Garfield announced that zoning and coal-price restrictions would probably be removed Dec. 15 [1039].

Harrisburg, Penn.

The Pittsburgh & Lake Erie Railroad Co., the Erie Railroad Co., the Bessemer & Lake Erie Railroad Co. and the Northwestern Pennsylvania Railroad Co. were ordered by the Public Service Commission on Dec. 11 to make effective in two weeks a joint rate of $1.55 per ton on bituminous coal delivered from the mines to Edinboro, Penn., on complaint of the Edinboro State Normal School that the railroads had failed to comply with a similar order issued by the commission last April. The commission retains jurisdiction in the case to ascertain the amount of damages due the complainant by this failure to comply since the issuance of the first ruling.

Profiteering in coal, sold by the bucket or small quantity to the householders, will be prevented in Philadelphia, and the peddlers and storekeepers will have no chance to duplicate conditions in New York, where as high as $40 per ton has been charged by coal gougers. Dealers in nut and pea coal are obliged to sell at a price set by the Fuel Administration and are restricted by the Bureau of Weights and Measures from giving underweight.

Storekeepers are licensed to sell nut when in bags of 25 lb. net weight, at 19c.; pea in bags of 25 lb. net weight, 16c.; nut in 10-qt. buckets, containing not less than 18¾ lb., 13c.; pea, in 10-qt. buckets, containing not less than 18¾ lb., 11 cents.

From what railroad men say, and what railroad and state police say in corroboration of them, there is not much stealing of coal considering the large amounts that are being hauled every day. Last year, owing to the severity of the weather, there was some annoyance because of the way cars were raided, but this year there has not been much doing along that line. The strict policing has prevented much of the coal picking that used to go on, while the gangs that used to jump coal trains and throw off coal have been fairly well broken up throughout the state.

Charleston, W. Va.

Production in the Tug River and Pocahontas fields at the present time is about 100,000 tons a week under the maximum mined during the war. The influenza epidemic has broken out anew, and this is chiefly responsible for the loss of man power. There has been no decrease in the amount of coal coked.

In the Fairmont region, during the week ending Dec. 7, production was maintained on the same level it had been throughout November, when a total of 24,184 cars were loaded. The car supply was exceptionally good at the beginning of the week, but on the last day of the week the supply fell short of requirements by about 500 cars. Much of the coal produced in the region in the first week of the month was used for railroad purposes, and between the demand from that source and the commercial sales, producers were rather elated over market conditions. In some quarters complaint was made that the market was somewhat stagnant.

Production was curtailed in the New River region during the week beginning Dec. 2 by serious labor troubles combined with more or less sickness in certain localities. While New River coal had accumulated to some extent at Newport News and Locust Point, this did not materially interfere with shipments. As against a gross tonnage output during the last week of November of 233,000, only 216,540 gross tons were produced during the first week of the month, a decrease of 16,000 gross tons. There is an excellent demand, generally speaking, for New River smokeless.

There has been no effort to restrict production in the Kanawha region, even though the product of the district is shut out of certain eastern and western markets by zone restrictions. During the first week of December the total net tonnage produced was 148,434 tons, a decrease of 3000 tons, the principal production loss being due to labor shortage. The car service during the week was ample for all requirements. However, 21 mines did not submit a report.

There was a sharp decline in production in the Roaring Creek field during the first week of the month due solely to labor troubles. Further south, on the Coal and Coke, influenza had spread rapidly and many operations were affected.

Perceptible improvement was shown in the production record of the Logan mining district during the week ending Dec. 7, the output for that week reaching a total of 210,934—a tonnage of nearly 80,000 in excess of that for the final week in November, when only 131,797 tons were produced and when only 47.80 per cent. of the full tonnage of the district was produced, as against 78.89 per cent. the first week of December. Production losses from "no market" in this district were reduced from 123,305 tons to 19,117 tons, or from 44.72 per cent. to 7.15 per cent. of the full capacity of the mines. The car shortage was almost negligible.

Birmingham, Ala.

Despite the ravages of influenza, operators in the Birmingham district are optimistic over the prospects faced with the coming of the new year. The demand supplied by the mines in this section is steadily showing an increase with the removal of all Government restrictions on storage of coal by firms and individuals.

Mobile is handling greatly increased steamer tonnage, and the demand for bunker coal from that port, as well as from New Orleans, is such that many cars are being used to make shipments there. The entire equipment for Warrior transporta-

tion is being used in this trade also. A goodly quantity of domestic coal is also being shipped in that direction.

Coal experts throughout the district, despite the influenza situation, expect production to show an increase shortly. However, if such an increase is recorded, it will not be due to the letting up of the epidemic, but to the redoubled efforts which miners are making at the urgent appeal of union officials and organizers.

Differences between operators and miners as to when the present contracts are to become void have become an issue in the district, but no trouble is anticipated at present, as union officials and organizers of the United Mine Workers are going to the various camps and appealing to the men to continue working under the war contracts. Throughout the district Sunday, Dec. 8, the officials were making talks at camps in the district and asking for increased efforts to meet the demand for fuel to be used in converting the industries of the country from a war to a peace basis.

The labor problem is expected to become a dead issue with the discharge of many thousands of men from Southern camps. Already Federal labor directors are writing to corporations here, asking how many men they can use. Advantage is being taken of this opening by many operators.

Coke manufacturers report an excellent demand for their product, being full up with contracts at present. Additional orders are being refused by nearly every operator in the district. The foreign demand for this commodity is showing a steady increase. Most of the export trade from the district is with Mexico.

PENNSYLVANIA

Anthracite

Nanticoke—In an announcement made public on Dec. 10, General Manager Robert A. Quin, of the Susquehanna Collieries Co., stated that the management had made arrangements whereby all former employees now with the colors will obtain their former positions when they return home. Nearly 800 young men are affected by the company's decision.

Drifton—Tuesday, Dec. 24, has been selected as the date for the annual festivities which surround the Coxe Christmas tree in Cross Creek Hall, where thousands of little ones of the mining towns in this community will be remembered with substantial gifts. The giving of toys and wearing apparel will be omitted this year, a cash donation and candy taking the place of these.

Shamokin—Ex-sheriff W. E. Taby, of this city, and a number of others are erecting a large washery at a point in the creek channel midway between Green Ridge and Atlas. Already the framework for the structure is raised and within a short time the culm and coal in the creek channel will be run through the washery for market. A spur of railroad has been run to the structure. The building of the washery was held up for some time because of a dispute between coal companies as to ownership.

Bituminous

McDonaldton—The Brothers Valley Coal Co. has contracted with the Roberts & Schaefer Co. for the installation of a coal storage plant, to be installed in connection with the tipple at Mine No. 3.

Charleroi—The Winstead Coal Co. has received a Federal permit to construct a coal tipple, three ice breakers and four dolphins on the right bank of the Monongahela River, about 2400 ft. above Lock No. 8, near Point Marion, on the Fayette County side of the river.

Pittsburgh—The Pittsburgh Coal Co. is opening a large new mine, to be known as Montour No. 10. It is located on the Montour R. R., near Library, Allegheny County. There will be two drift openings, one on each side of a wide ravine about on the railroad grade. The coal from each opening will be conveyed to tipple height by chain car hauls, the tipple spanning the ravine. The coal will be screened on two Marcus screens, of 300 tons per hour capacity each, furnished by the Roberts & Schaefer Co., of Chicago. The mine is being equipped for a capacity between 4000 and 5000 tons per day and will be modern in every respect. A large town will also be built to accommodate the employees.

Uniontown—Additional coal lands owned by J. V. Thompson, bankrupt, have been disposed of for a total of $2,154,870.27, according to announcement made on Dec. 10. The deals have been completed, it was stated, but are subject to the approval of the creditors of Thompson, who will meet Jan. 7. The biggest of the deals was with James Edward Dorsey, of New York City, who purchased 2566 acres in Cumberland, Monongahela and Dunkard townships, Greene County, for a consideration of $1,460,098.03. The average price per acre was between $625 and $650. Another deal was with H. G. Rockwell, of Chicago, who purchased 1177 acres in Whittley and Franklin Townships for $450,645.80, the price per acre ranging from $300 to $400. About a dozen individual purchases were made.

WEST VIRGINIA

Huntington—Equipped with a new high-tension power plant in operation, the Coneva Coal Corporation of Chavies, Ky., has greatly increased its output. The company has installed an electric fan at its No. 2 mine and is preparing to begin operations at the No. 3 mine. Within a short time a 500-ton storage bin will be available for use. The company also contemplates installing storage-battery gathering motors.

Huntington—During the first week in January the Solvay Collieries Co. will start the publication of a magazine for free circulation among its employees at its fifteen mining plants in West Virginia and Kentucky. The publication office of the magazine will be in Huntington. The new publication is to be known as "Solvay Folk," and George C. McIntosh, who recently resigned from the Bureau of Information, United States Fuel Administration, will be its editor.

Richard—A conflagration destroyed the greater part of the plant of the Elkins Coal and Coke Co. at this place, on the night of Thursday, Dec. 5, only a few fireproof buildings escaping destruction. The loss to the company is estimated at approximately $50,000, partly covered by insurance. The fire had its origin in the engine room of the crusher plant. Though the company has its own fire-fighting apparatus, the flames, fanned by a high gale, spread rapidly, burning to the ground the tipple, crusher plant, supply trestle, power house, etc. On the morning following the fire the work of reconstruction was begun, and although it was necessary to order much new material and machinery, General Superintendent J. B. Hansford expected to be able through hastily improved means to resume producing coal within a few days.

Fairmont—Jacob F. Straight, who is now secretary of the Fairmont and Cleveland Coal Co., will sever his connection with that corporation in an official capacity on Jan. 1. Mr. Straight has disposed of a portion of his holdings to William E. Watson, Jr., and associates. The Fairmont and Cleveland Coal Co.'s operation is known as the Parker Run mines at Rivesville, where the Sewickley seam is being worked. Mr. Straight has retained a considerable portion of his holdings in the operation. He has not decided as yet whether he will reenter the coal business.

TENNESSEE

Knoxville—The tipple and chutes of the Wisconsin Steel Co. coal and coke works, at Benham, Ky., were destroyed by fire Dec. 2. The loss is considerable, as the company had remodeled the plant in 1916 and 1917 at a cost of approximately $50,000, putting in up-to-date screens with pendulum hangers, boom conveyor leaders, box-car leaders, conveyors, etc., and replacing part of the structure over the loading tracks with steel. The company is producing some coal from new mines recently opened across Looney Creek from the original opening, but the old mine and the 408 beehive ovens will be idle until the tipple can be rebuilt.

INDIANA

Petersburg — Arrangements are being made for the installation of the big new steel tipple at Atlas mine No. 1, north of Petersburg. The structure, which is to replace the big tipple destroyed recently by fire, is to cost $156,000, will be 96 ft. high and built to handle 4500 tons of coal daily. Big washeries will also be installed. Workmen have begun labor upon a washhouse which will accommodate 450 miners. One hundred and fifty new cars have been shipped to the new Atlas mine and switch room is being made for sixty empty coal cars a day. More than $300,000 will be spent in improvements this winter and early next spring.

ILLINOIS

Carlinville—The purpose for which the Standard Oil Co. is sinking its great mines at Shoper, near this city—to furnish coal for its vast oil refineries—is about to be realized, for within a few days the first consignment of coal will be shipped to Whiting, Ind. The coal will be routed over the Northwestern, and Trainmaster Culp of that road has been in Carlinville and vicinity conferring with local railroad men as to the proper handling of coal. The first shipment of coal will come from what is known as Mine No. 3, which has been opened with marvelous rapidity, considering the size of the shaft. The railroad between Carlinville and Shoper has been completed as far as the Northwestern tracks, and a shuttle train will be run just as soon as the coach arrives. This will take the workers to within half a mile of the mines and will enable them to live in Carlinville. The road will be completed into the mine just as soon as the viaduct over the wagon road can be built and the dam of the reservoir completed. The dam will be used as roadbed.

Lincoln—Coal miners who failed to file income reports last January to April are being interviewed by a deputy internal revenue collector from the office of J. L. Pickering, of Springfield.

Decatur—So well have the people of Decatur and Macon County stocked up on their winter's supply of coal that the miners state that they will have a regular "summer" season, as far as work is concerned. All summer the local mines were working at capacity digging coal to fill the basements of Decatur homes and the yards of Decatur industrial plants. Now the mines are running only part time and the miners are receiving only about half the usual pay.

West Frankfort—The Byproducts Coal Corporation is installing 500 kv.-a. at Mine No. 19 and 550 kv.-a. at Mine No. 18. The company was purchasing power from the Central Illinois Public Service Co., but was compelled to make the installation because the service company rendered unsatisfactory service. A 72 x 18 horizontal tubular boiler is also being installed at Mine No. 18.

The Old Ben Coal Corporation is sinking a new mine two miles southwest of West Frankfort. It is now down 165 ft. and is going to a depth of 420 ft. The main shaft is 12 ft. 8 in. by 22 ft. Coal only is to be hoisted at the main shaft. The air shaft is 12 ft. 8 in. by 24 ft. Men and material are to be hoisted and lowered at air shaft only. The capacity of the mine is expected to reach 5000 tons a day. A temporary steam hoist is to be used, but later an electric hoist is to be installed. Mine is to be electrically operated below with 20 locomotives and 35 machines. Building is to be of high-roof type and of brick and steel sash construction. Energy will be secured from Mine No. 11 at Christopher, Ill., and No. 9 at West Frankfort.

OKLAHOMA

Okmulgee—Purchase of the Okmulgee County properties of the Blackstone Consolidated Coal Co. by M. C. Rosenbaum, of New York, and G. G. Gillette, of Tulsa, and the fact that the new owners of the Blackstone property were working on a plan which would lead to the construction of a direct route from Oklahoma City to Okmulgee and Henryetta was announced recently. The coal mine of the Blackstone company near Schulter has already been taken over by the new owners and the mine is being completely equipped with modern electric coal-mining machinery. The mine is now producing between 400 and 500 tons per day, and when all the new equipment is installed the mine will produce about 1000 tons a day.

BRITISH COLUMBIA

Nanaimo—One of the smaller powder houses of the plant of the Canadian Western Fuel Co. was completely obliterated recently by an explosion the cause of which is a mystery. Fortunately the accident happened when there were only a few men in the vicinity, and no one was seriously injured. It is thought that some detonators were left in the building by mistake and that the explosion was the result of some of these falling to the cement floor.

Princeton—Fire in the workings of the Princeton colliery interfered with operations toward the end of November. It is now well under control, however, and work is proceeding.

Prince Rupert City—The Telkwa collieries, situated on the line of the Grand Trunk Pacific Railway Co., northern British Columbia, are finding some difficulty in keeping coal moving from the mine to provide the domestic needs of Prince Rupert City and the adjacent district. Jabe Ashman, the superintendent, asserts that there is plenty of coal in the bunkers but, because of bad roads and for other reasons, there has been delay in arranging for its transportation.

New Westminster—That the British Columbia collieries are exporting coal before fully providing for the domestic needs of the Province is a charge made by the civic authorities of New Westminster. In a recent discussion of the fuel situation in this city it was stated that the dealers did not

have their normal supply of coal and, if exceptional conditions arose, a serious shortage might develop. It was decided that Nichol Thompson, Fuel Controller, be requested to see that all home demands were filled before the collieries were permitted to fill export orders. Incidentally the action of Mr. Thompson in allowing the dealers to raise their price to the consumer 65c. a ton following an advance in miners' wages of 75c. a day was criticized, it being pointed out that the per capita rate of coal production at the mine was 5½ tons a day. One of the aldermen, taking the viewpoint of the dealers, sarcastically observed that "it pays to increase wages."

Personals

J. W. Powell, mine manager at the Cassidy's colliery of the Granby Consolidated Mining and Smelting Co., Cassidy's, B. C., has resigned and has been succeeded by **James Hargreaves.**

M. L. O'Neil, of Morgantown, W. Va., superintendent of the Connellsville Basin Coke Co., has resigned that post to become superintendent of the New York Pyrites Co., a New York concern.

M. R. Evans, formerly senior inspector with the Associated Companies, has resigned to accept the position of safety engineer for M. A. Hanna & Co., of Cleveland, Ohio, with headquarters at Wilkes-Barre, Penn.

Louis H. Spier, formerly with Olin J. Stephens, Inc., New York City, has been appointed general manager of the coal business of Joseph Gordon, at the foot of East 38th St. Mr. Spier was connected with the Stephens Co., one of the largest coal concerns in The Bronx, for more than 20 years.

P. C. Thomas has been chosen as general manager of the East Gulf Coal Co., headed by P. M. Snyder. Mr. Thomas' headquarters will be at East Gulf, W. Va., in the Raleigh County field. Up until the time he accepted his new position Mr. Thomas was assistant to the general manager of the New River Coal Company.

F. H. Watson, who has been district manager in charge of the Columbus office of the George M. Jones Coal Co., of Toledo, has resigned to accept the sales managership of Monsarrat Brothers, an operating concern of Columbus. The Monsarrat interests control extensive properties in the Hocking Valley and have a daily output of about 1500 tons. Mr. Watson assumed his new duties Dec. 10.

Obituary

John Kerr, of Fayette City, Penn., district mine inspector for the Pittsburgh Coal Co., died Dec. 8 of influenza.

Hugh Sloan, shift boss at the Cassidy's colliery of the Granby Consolidated Mining and Smelting Co., Cassidy's, B. C., died recently from pneumonia following an attack of influenza.

John J. Cannon, chief engineer of the Guerber Engineering Co., Bethlehem, Penn., died of pneumonia on Sunday, Dec. 18. The deceased was 31 years of age. Mr. Cannon was partly or wholly responsible for the designing and erection of the majority of the coal structures in the anthracite fields of Pennsylvania.

William Cameron, for many years secretary of the St. Louis Coal Traffic Bureau and chairman of the St. Louis East End Bound Freight Committee, and who has had charge of coal-tariff making in St. Louis for many years, died in a sanitarium in Denver, where he had gone for his health. He is survived by his widow.

William Lewis Phillips, ex-President of District 18, United Mine Workers of America, which includes the eastern British Columbia and Alberta coal-mining camps, who left Fernie, B. C., with the 225th Overseas Battalion C. E. F., has been reported killed in action on Sept. 28 last. Thomas, a brother, was officially reported killed on Sept. 29, the day following. W. L. Phillips first came to Fernie from Wales seven years ago and was employed on the engineering staff at the Crowsnest Pass collieries. After holding minor offices in the Fernie Union, he was elected to the post of President of District No. 18 in 1914. After the expiration of that term he was reëlected but resigned before the end of the year in order to take up arms with the Canadian forces. Two brothers, David E. and Richard S., are residents of Fernie.

Industrial News

Cape May, N. J.—The Government has completed plans for the construction of a new coal-storage building at the local naval air station. The structure is estimated to cost $50,000.

Chicago, Ill.—W. F. Keckeisen, formerly advertising manager of the International Filter Co., and previously associated with the Federal Sign Co., has joined the staff of Russell T. Gray, advertising engineer, Chicago.

New York, N. Y.—The Bertha Coal Co., of Pittsburgh, Penn., has opened a New York office in the Hudson Terminal Building, in charge of Dr. Henry M. Payne, assistant to the president, and George N. Reed, Eastern traffic manager.

Punxsutawney, Penn. — The Onondaga Coal Mining Co., of Punxsutawney, has contracted with the Roberts & Schaefer Co. for the rebuilding of the steel tipple at this point. Marcus screens, rock disposal machinery and boiler house coal equipment will be provided for.

Ironton, Ohio—The Ironton Engine Co. announces that it has discontinued its branch office at Pineville, Ky., and has opened an office at 1501-1502 Fayette National Bank Building, Lexington, Ky. W. H. Patton, who was formerly located at Pineville, will be in charge.

Elkins, W. Va.—An operation will be established in Barbour County by the Row Coal Co., which will open a coal mine near Junior. The new company has an authorized capital of $20,000. The incorporators are W. A. Row, W. J. Row, G. F. Row, L. H. Row and Cora V. Hillyard, all of Junior.

Charleston, W. Va. — Capitalized at $25,000, the Barbe Coal Co., of Morgantown, will have its plant in Harrison County, where a tract of coal land will be developed. The organizers of the company are W. D. Reed, of Fairmont; Victor E. and Edith Barbe, of Clarksburg; Guy Hall and Mabel Wilson, of Morgantown.

Charleston, W. Va.—Reconstruction work on the railroad connecting its Coal River properties with the Chesapeake & Ohio R.R. near Seth has been virtually completed by the Federal Coal Co., which will develop leases in the Coal River section as well as on the extension of the Kanawha & Michigan Ry. in Nicholas County.

Morgantown, W. Va.—Operations both in Monongalia County and in Preston County, West Virginia, will be established by the Wilmoth Coal Co., financed by Connellsville capital, the new company having an authorized capital stock of $95,000. The incorporators are S. R. Goldsmith, W. S. Metz, Emanuel Horvetz, J. C. McClenen and C. S. Pore, all of Connellsville.

Wenatchee, Wash.—The Wenatchee Apple Orchard Co. has let a contract for the sinking of a 300-ft., double compartment shaft to tap a 12-ft. vein of coal which diamond drill tests have shown underlie the company's entire 1100-acre property in the Moses Coulee district. Government and state experts have pronounced the coal equal to any mined in the state.

Columbus, Ohio—The George M. Jones interests, of Toledo, Ohio, operating the Ohio Collieries Co., in the Hocking Valley, and the Cambria Collieries Co., in eastern Ohio, will not fill the vacancy created by the resignation of W. Guy Srodes, assistant general manager, recently announced effective Dec. 16, but the position will be filled by G. S. Jones, secretary of the companies.

Philadelphia, Penn.—By the installation of new pumps at the Lardner's Point and Roxborough pumping stations, the city water department has effected a saving in coal alone of 20 tons per day at each plant. It has only been a year since that by the introduction of new stoking devices these plants were enabled to change from rice coal to the smaller anthracite sizes.

Toledo, Ohio—The Hocking Valley docks at this place loaded the last coal for the season on lake vessels during the past week. The amount loaded was 29,144 tons. The total loaded by the docks for the season was 5,161,626 tons as compared with 4,937,000 tons during the season of 1917. The season as a whole was one of the most successful in the history of the lake trade.

Atlantic City, N. J.—The Board of Directors of the National Coal Jobbers' Association, at its meeting held here on Dec. 5, decided to change the name of the organization to the American Wholesale Coal Association. The change becomes effective on Jan. 1, 1919. George M. Dexter, of Dexter & Carpenter, New York City, is the president. L. Romanski is the secretary-treasurer of the association.

Oklahoma City, Okla.—The Producers and Consumers Coal Co. has been organized at Miami, Okla., and charter has been issued by Secretary of State Lyon at Oklahoma City. The company is capitalized for $100,000 and the incorporators are J. R. Cavanaugh, E. M. Smith and C. R. Jordan. The company owns leases to a considerable acreage of coal lands. It will mine coal and also conduct a retail coal business in Shawnee.

Harrisburg, Penn.—The Pennsylvania State Compensation Board has rendered a decision holding that a miner who injures himself in an effort to shut down mining machinery when a cable slips or other interference in operation occurs, is entitled to compensation when the accident is in discharge of his duties in order to prevent mishap at the works. The Board ruled that this is "an untoward event which is not to be expected."

Scranton, Penn.—In a suit brought by Herman F. Trager against the People's Coal Co. to recover for damages to his property brought about by mine settlings in West Scranton, the jury awarded plaintiff $26,500. The verdict is the largest ever returned in a case of this kind in the county. The coal company made no denial that it was liable for damage, but objected to the price asked by Trager, and against any punitive damages. Counsel for the defense will ask for a new trial.

Columbus, Ohio—The properties of the King Coal Co. and the Tidewater Coal Co., located in the Pocahontas field and owned largely by C. H. Boardman, of Columbus, have been taken over for the purpose of operation by the Houston Coal Co., of Cincinnati. The shipping point is Vivian. Mr. Boardman retains his interests and the change was made to relieve him of much of the responsibility. A large part of the tonnage will continue to be sold through the Interstate Coal Co., of Columbus.

Louisville, Ky.—Coal men from various sections of the Ohio valley were present at the two-day session of the Ohio Valley Improvement Association, which adjourned on Dec. 12. The organization adopted resolutions calling upon Congress for larger appropriations to hasten the work of completing the nine-foot stage of locks and dams from Pittsburgh to Cairo. Attention was called to the fact that during the past fall more coal was handled through the partly completed locks and dams by means of artificial rises than ever before in the history of the river.

Orange, N. J.—The Edison Storage Battery Co. announces the appointment of George Simons as district sales manager of its Detroit district. Mr. Simons succeeds Bertram Smith, who was recently called to the main office at Orange, N. J., in the capacity of assistant general sales manager. Mr. Simons has been associated with the Edison Storage Battery Co. for the past three years. He has had valuable experience in storage-battery practice, and previous to his coming to the Edison Storage Battery Co. was for nine years associated with the old National Battery Co., Buffalo, N. Y., and with the United States Lighting and Heating Company.

New York, N. Y.—The advisability of separating the Byproduct Coke Producers' Association into two groups was discussed at a meeting of the organization in the Hotel Knickerbocker this city, on Monday and Tuesday of this week. The object is to have the producers east of the Mississippi represent one group and the producers on the Atlantic coast and Middle Western points represent the other group. With the fuel restrictions practically removed, it was explained at the meeting it is intended to acquaint the public with the possibilities of coke, with a view of increasing its domestic consumption. Among the speakers was W. S. Blauvelt, Director of the Division of Coke of the Fuel Administration. J. D. Forrest, of Indianapolis, presided.

St. Louis, Mo.—Recommendation has been made by John C. Hall, director of enforcement of fuel regulations in Missouri, to the enforcement division of the Federal Fuel Administration that the St. Louis branch of the Searls Coal Co. be required to refund to the Light and Development Co., of St. Louis, $2,269.88, which it is alleged to have collected through overcharge for coal. The complaint of the light and development company is that since July 5 it has been charged by the Searls company $2.17 a ton for coal described as modified mine-run, which was in reality 2-in. screenings, for which a charge of only $2.05 should have been made. E. B. Cullman, manager of the company, called before Hall, refused to make a statement.

MARKET DEPARTMENT

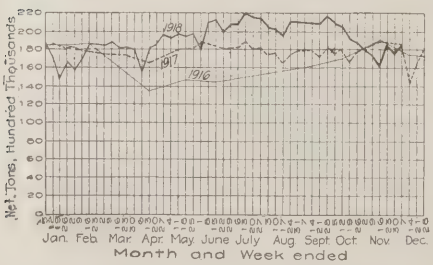
Weekly Review

No Change of Any Account in Market Conditions—Soft Coal Buyers Not Eager for Fuel—Many Mines Forced to Curtail Operations—Anthracite Situation Improving

NO CHANGE of any moment can be looked for in the coal market until the arrival of real cold weather. Bituminous coal is plentiful in spite of the fact that output has fallen off considerably during the past two months. Consumers of soft coal are resorting to their reserve stocks for their current needs, not coming into the market at this time in the belief that the elimination of Government prices is imminent and that coal will be cheaper before long.

As a direct outcome of the decision on the part of buyers to stay out of the market many mines are working only part time, particularly in the Middle West, where only the demand for railroad coal prevents complete cessation of operations at a number of plants. Government prices are holding up rather well.

Present industrial requirements of those who have no large stocking facilities are being filled without any difficulty, bituminous production being maintained at an average of 1,835,000 net tons a day. The total output of soft coal from Apr. 1 to Dec. 7 of the present coal year is placed at 420,731,000 net tons as against 382,708,000 net tons for the like period of 1917.



No extremely urgent need for anthracite coal is in evidence. Production increased slightly during the week ended Dec. 7, with the shipment of 1,807,000 net tons. The total hard-coal output from Apr. 1 to Dec. 7 is 68,778,000 net tons, compared with 70,397,000 net tons in 1917.

Weather conditions have been favoring the consumer of anthracite, and the educational campaign inaugurated by the Fuel Administration to teach users the utility of the smaller sizes of hard coal has helped ease the situation. It has resulted in somewhat decreasing the demand for the hitherto favored larger sizes. The Fuel Administration has demonstrated that Buckwheat No. 1 can be burned efficiently and economically in household ranges, and it would prove no surprise if consumers showed a more decided preference for this size in the future.

There was a time when pea coal was considered a steam size solely; now it has taken its rank as a domestic size. No fear need be entertained of a coal shortage at any time if more consumers turn to the use of the smaller coals, as these are always plentiful and cheaper than the larger coals. When handled intelligently the small sizes give just as satisfactory results as the larger sizes, which are in short supply.

WEEKLY COAL PRODUCTION

Production of bituminous coal in the week ended Dec. 7 is estimated at 11,008,000 net tons, an increase compared with the week of Nov. 30 of 1,312,000 tons (or 13 per cent.) but 1,135,000 tons (or 10 per cent.) below the corresponding week of 1917. From the reports of operators it is estimated that the average number of days worked in Thanksgiving Day week were 5.3. The average daily output that week is shown as 1,830,000 tons compared with 1,835,000 tons in the week of Dec. 7,

a six-day week. The influenza epidemic is still interfering seriously with production in the eastern fields, and production of domestic sizes of coal in the fields supplying the Atlantic seaboard and southern states is not up to requirements.

Production of anthracite in the week ended Dec. 7 is estimated at 1,807,000 net tons compared with 1,613,000 tons the previous week and 1,778,000 tons in the corresponding week of 1917. The total production from Apr. 1 to date is estimated at 68,778,000 net tons compared with 70,397,000 tons in 1917, a decrease of 1,600,000 tons, equivalent to about 850,000 tons of domestic sizes.

Reports from the railroads for the week from all districts compared with the week ended Dec. 7 show increased shipments from all districts compared with the week of Nov. 30. Compared with the corresponding week of 1917, the only districts recording greater shipments were Fairmont, Ohio, southern West Virginia and southwestern Virginia.

The final report of Lake shipments for the season shows 28,153,317 net tons of cargo coal, a new high record, and slightly in excess of the program of 28,000,000 tons established early in the season. Shipments in the week ended Dec. 7 were 80,580 tons. It is interesting to note that although the Lake traffic in 1918 was greater than in 1917, the vessel fuel used was less than 1,600,000 tons in 1917 against 1,300,000 in 1918. This is attributed to the fact that with fewer vessels in the trade in 1918 there was less movement of steamers either up or down the Lake without cargo.

Bituminous coal shipped to New England for the week ended Dec. 7 is estimated at 328,897 net tons, a decrease of 8.6 per cent. compared with the week preceding. Rail shipments—92,352 net tons—decreased 12.4 per cent. and tidewater shipments—236,545 net tons—decreased 0.7 per cent. Baltimore was the only harbor to report an increase in shipments. Shipments from Hampton Roads decreased 14.3 per cent. and from New York 4.8 per cent.

Total shipments for the coal year to date are estimated at 20,038,000 net tons, or 0.8 per cent. ahead of budget. Rail shipments, amounting to 7,573,311 net tons are 5.4 per cent. ahead of budget, while tidewater shipments, amounting to 12,464,586 net tons are 1.8 per cent. behind budget. Shipments from New York, Philadelphia and Baltimore are slightly in excess of budget, but Hampton Roads is 3.3 per cent. behind.

Tidewater shipments of bituminous coal for the week ended Dec. 7 were 718,738 net tons, 10.8 per cent. higher than for the week preceding. Shipments from Hampton Roads decreased slightly; New York and Philadelphia increased 21.3 per cent. and Baltimore, 5.2 per cent. For the coal year to date tidewater shipments amount to 31,550,000 net tons, approximately 10 per cent. ahead of the budget established by the Fuel Administration. Of this total nearly 15,000,000 net tons have been shipped through New York and Philadelphia, 2,848,000 net tons through Baltimore and 13,785,000 net tons through Hampton Roads.

The production of beehive coke in the week ended Dec. 7 is estimated at 543,000 net tons, an increase compared with 522,000 tons in the week of Nov. 30, but a considerable decrease compared with 695,000 tons in the corresponding week of 1917. Production of beehive coke is now below that of byproduct coke, but the total coke output is above that for last year. Operators in the Connellsville, Greensburg and Latrobe districts report for the week ended Dec. 7 the production of 307,112 tons of coke compared with 291,972 tons the previous week. The gain was the result of better labor supply. The same operators shipped 159,700 tons of coal in the week of Dec. 7 compared with 160,500 the week of Nov. 30.

The production of byproduct coke in the week ended Dec. 7 was 578,139 net tons compared with 572,239 tons the previous week and 429,000 tons in the corresponding week of 1917. The percentage capacity produced is reported as 88.7 against 87.9 in the week of Nov. 30. Losses aggregating 5.1 per cent. of capacity are reported as the result of repairs being made to plants and 3 per cent. for other causes, among which are noted operation on extended working time and using coal from stock pile that gave coke difficult to "push." The loss of 37 per cent. of production because of no market for byproduct coke in Massachusetts is to be noted.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running about even with the coresponding week of 1917. Road sales for immediate and future delivery were less than for the same week of last year. The number of customers in the house was about the same. Retail business in holiday merchandise continues excellent. Collections are good.

Dry Goods Economist—During the week two important developments have occurred in the textile situation. First, the Government has decided to sell gradually its stocks of wool. Auctions will be held periodically, but efforts will be made to avoid any unnecessary or sudden effect on prices. Second, the Department of Agri-

culture has announced that its final estimate of this year's cotton crop is 11,700,000 bales, exclusive of linters. This quantitiy is approximately 400,000 bales in excess of last year's yield. Some of the big woolen and worsted plants that had been seized as enemy-owned have been sold by the Alien Property Custodian. The other seized plants are to be sold in the near future.

American Wool and Cotton Reporter—That wool held by the Government is to be offered for sale at public auction is an announcement greeted with considerable satisfaction by the wool trade. It is understood that the amount of wool to be offered at each sale will be such "as in the opinion of the wool experts the market can easily absorb." A minimum reserve price will be fixed, below which no bids will be entertained. Removal of restrictions against foreign and speculative short selling cotton contracts has put the trade in a more satisfactory position. Cancellations are raising ructions in the cotton market but there does not seem to be any question that practically all of the goods manufactured for the Government can be disposed of.

The Iron Age—Unexpectedly the general committee of iron and steel manufacturers reported to a large meeting of producers in New York, Dec. 9, in favor of a "moderate" reduction in prices of pig iron and all rolling mill products effective Jan. 1. It is expected that pig iron will be reduced $3, plates and shapes $5, and sheets and tinplates, $10 per ton, with other prices in proportion. The past week has brought further export and domestic business to the steel companies, some of them booking more than their current output; but, as heretofore, it was an aggregate of small replenishing orders. The belief that with the heavy cancellations by England, France and the Government at Washington, demand for some months would fall below capacity is still the dominant consideration.

Bradstreets—Plans are being formulated by leading lines to vigorously go after business in the new year, but it is conceded that the campaign will have to overcome the waiting attitude of smaller dealers, most of whom are strongly wedded to the belief that prices will work downward. Best reports as to distribution come from the northwest, trading in that zone being singularly free from the uncertainties that beset every other part of the country. In industrial lines, readjustments of war contracts, branching out for peace-time trade, and the absorption of labor that has been liberated from war work, proceeds apace. Labor is restive, fearing the effects of readjustments, and supplies, especially of less efficient help, are better, but as yet congestion is not in evidence, and the government is endeavoring to place men before freeing them from camps.

Atlantic Seaboard

BOSTON

Situation is mixed. Water-borne coal goes begging while all-rail deliveries are increasingly hard to get. Trade much interested in probable attitude of labor. Only light inroads made on reserve stocks. Hampton Roads shippers at loss to place coal here are using every means to load offshore or ship west. Little inquiry for coals over New York piers. "Storrow bituminous" now practically cleaned up. Rail movement drops below 300 car daily average. No indications of lower prices f.o.b. mines. Talk of spring prospects. Differentials a matter of some anxiety. Coastwise freights the important factor. Anthracite receipts show slight improvement. Complaint of volume of desirable sizes still coming forward for distribution by New England Fuel Administrator. "Independents" not held to the line as strictly as companies. Retailers getting overstocked with pea while fuel authorities solicit orders for stove and chestnut.

Bituminous—The current market is in a confused state. At the various distributing plants where coal is forwarded inland it is next to impossible to dispose of cargoes in the open market, and at the same time the few buyers who are trying to secure deliveries all-rail find it difficult to do so for anything like prompt shipment. We have steamers in over-supply along the coast and we have long lines of empty coal cars stored on the railroads, although for somewhat different reasons. All-rail the coal is not being produced, and coastwise there are no buyers. Everybody is waiting to see what will happen and from day to day, there are almost no developments. The present wide differential between rail and water delivery, in favor of the rail route, is one element in the situation, and the reserve stocks now in New England are what have saved buyers here from what would have been a most embarrassing situation. It so happened that rail shipments sagged off just at the time when New England consumers had become so well stocked that all buying interest disappeared. If the reserve supplies had not been taken on early and steam-users had been obliged to buy water coal to a much greater extent at the higher price level there would have been a lot of dissatisfaction. It may be that stocks are larger than ever before, but as it has turned out it has been no small advantage to a great many to have had their coal all-rail and during a season when it could be had in volume.

The only price shading that has come to notice has been in the case of water coal at distributing points like Boston and Providence. These instances are very few, however, for all the regular shippers have been extremely cautious about sending coal forward unsold. Needless to say every contract has been right up to quota on water borne coal and only the more reckless would take chances with such a market as prevails at all the New England re-handling points. Tidewater coal with its high marine freights and demurrage and other charges is going begging at this writing, and it is doubtful if there will be any inquiry worth mention until March or April.

All-rail prospects are bound up with the probable attitude of labor. Current reports of idleness in the region and generally light production with a great surplus of cars tend to show that output will not increase until the market calls loudly enough for increased shipments to eliminate all possibility of a reöpening of wage discussions. The mine-workers will make every effort to keep wages on at least their present level and one of the most effective methods to that end will be a decreasd production until the market is again in shape to take coal in large tonnages. It looks therefore as if there would not be any free movement of coal until present stocks have been worked down.

The number of bottoms loading at Hampton Roads for New England has steadily decreased and practically all the agencies are hard put to it to find outlet for the heavy volume of coal now being poured from Pocahontas and New River districts to the piers. Suspended shipments are the order of the day, and every effort is made to increase shipments offshore, to the line trade, and of prepared coal for the west. Difficulties of export license and securing ships for certain destinations are clearing up somewhat, and it is predicted that offshore dumpings will continue to increase.

Coal over the New York piers is also rather druggy. Inquiry on Long Island Sound has again dropped off, and it is likely there will be little call for deliveries in barges for the balance of the winter, unless the shortage of rail coal should become really acute. The better grades are moving rather easily, but less desirable coals meet with practically no demand. Bunker requirements are not yet heavy, but it is certain they will improve.

For the first ten days of December the receipts of bituminous at the five New England gateways have averaged only 290 cars, company fuel included. Compared with the November figures this is a further drop of nearly 100 cars daily, or less than 40 per cent. of the movement during September. Perhaps this is the most striking commentary that can be made today on the New England situation. It is on the basis of such facts as this that the trade is discussing spring prospects. The possibility of lower prices f.o.b. mines is heard less and less as the season advances, but there is a great deal of anxiety on the part of water shippers as to whether coastwise freights will be modified in season for next year's business. If the present differentials are maintained between water and rail deliveries the general state of the market will be decidedly awkward for everybody concerned, and it would seem that some measures are bound to be taken before long to remedy the discrepancy in price between the two routes. Marine freights then are the important factor in all calculations for the future.

Anthracite—Receipts of domestic sizes show some improvement, although the increase has not been large. The first 10 days of December showed a daily average of 371 cars as compared with the November average of 333 at the five New England gateways. By water there has also been a slight improvement, but tonnages are apt to be misleading because so large a proportion of current shipments by water are sizes like broken and pea.

Through the anthracite committee requisitions and directions continue to be filed for stove and chestnut, the most eagerly sought sizes. Besides the sheaf of other demands through this channel there are still approximately 100 cars daily being shipped to the order of Mr. Storrow for disposition through his office. Retail dealers who have regular connections with large shippers are being told their requirements for stove and chestnut must wait until Government demands are met, and at one and the same time, the New England Fuel Administration, for instance, is in the proud position of actually soliciting consignments in order to dispose of the Government stove and chestnut being shipped to its order on a preferred basis. The Rhode Island Fuel Administration recently made an official announcement that all talk of a shortage of stove and chestnut on the part of retailers was nonsense, for that office had available for sale eight cars every day.

The plain truth of the matter is that the New England Fuel Administration should now cease taking "emergency" coal forthwith, for there are today no real cases of distress that cannot be met with better satisfaction and far more intelligently through regular trade channels. Acting on figures that are far astray, and taking no account of local conditions, embargoes are being declared against communities that are just getting on from hand to mouth, while in other instances retailers who have already had generous shipments are being flooded with "free coal," apparently for no other reason than their ability to send certified checks in advance.

NEW YORK

Surplus of anthracite steam coals puts salesmen on the road for the first time in nearly two years. Stove and chestnut sizes scarce, with egg and broken easier. Householders take to using buckwheat. Retail dealers well loaded with small coals. Present condition of bituminous market due to small production. Weather keeps down consumption and demand. Bunker coals move quickly.

Anthracite—Receipts here during the past week show a falling off from the previous week, but the increase in production reported the last of the week is encouraging. The lack of domestic coals is expected to be overcome by the middle of January. In the meantime the public has been educated to use pea and No. 1 buckwheat, which not only saves money for them now but will prove a greater benefit in years to come.

During the week ended Dec. 13 there were dumped at the local piers 6098 cars of all sizes of anthracite, as compared with 6127 cars the previous week.

The heavy call for stove and chestnut continues, but shipments of these sizes are slow. In many cases where they have been ordered by the consumer and where coal is urgently needed other sizes are substituted, provided the buyer is willing. However, there are many instances where the buyer, having had two-thirds of his order delivered, prefers to wait for the other one-third rather than take other sizes of coal.

The ending of Lake shipments this week will mean the diversion of a portion of that tonnage to this market, while further additions will be made as a result of the satisfactory conditions as a whole existing in New England, although there are some of the smaller towns along the coast that have not yet received their full quotas.

Broken and egg sizes are easier than either stove or chestnut, and because of the warm weather the entire situation is "looking up." Many wholesale houses, for the first time in nearly two years, have sent salesmen out to visit the trade. For the present they are looking for buyers for the steam sizes, but after Jan. 1 it is expected the heavy demand for all sizes will have subsided and buyers will be wanted to take care of the surplus.

Pea and No. 1 buckwheat are tightening because of the efforts of the dealers to substitute these coals for the larger domestic sizes. Rice and barley are long, and cuts in regular prices have been reported in order to move the surplus. Quotations ranging from $1.75 to $2 at the mines have been reported for barley.

The retail dealers are well supplied with the small sizes, some of them having so much in hand that they are refusing additional shipments. Labor troubles are facing the dealers in Queens Borough, their drivers asking a wage increase of $5 per week, with three deliveries a day. The dealers in other Boroughs may be asked to make similar increases shortly.

Current quotations, per gross tons, f.o.b., tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individual
Broken	$7.80	$8.55	Buck	$5.10	$5.90
Egg	7.70	8.45	Rice	4.65	5.10
Stove	7.95	8.70	Barley	4.15	4.30
Chestnut	8.05	8.80	Boiler	4.60	
Pea	6.55	7.30			

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—The demand for the better grades of coal is far in excess of the available supply. With the removal of the coal assigned to Pools Nos. 4 and 10 the coals suitable for commercial purposes have been greatly reduced. Coals for bunkers are moving freely, and there are sufficient bottoms here to take all that can be obtained. While the high grades of coals are scarce there is a fair supply of other grades, one shipper stating that early in the week he knew of 10 boat loads in the harbor waiting for buyers.

The market is uneasy. Buyers are in a quandary as to which way to jump. Many are of the opinion that notwithstanding the reports from Washington that the price restrictions will not be removed for the present, there will be something doing soon in that direction. Because of this uncertainty they have no desire to keep their bins filled. With the price restrictions removed some of the trade believe the market will settle to a steady basis.

The closing down of various branches of the steel industry has caused a surplus here of gas coal, but there is not sufficient to result in a price reduction.

Producers do not look for any considerable increase in production until after the New Year, and even then much will depend upon conditions such as transportation and temperatures. At present large consumers and public service corporations are well supplied with fuel.

Dumpings at the local docks for the week ended Dec. 13 amounted to 5250 cars, a decrease of 1200 cars from the previous week's figures.

Operations this week were slow. Some openings were closed while many others were able to work little more than half time because of the lack of help. Reports brought back from the mines by representatives of local houses indicate that many workers are suffering from illness and that those who are convalescent are not yet able to take up their regular work. Meantime empty cars are piling up.

Producers here are interested in the announcement coming from Washington that the War Trade Board has agreed to allow Holland 100,000 tons of coal, which is to be shipped in Dutch bottoms.

The first week of the existence of the Exchange Bureau of the Wholesale Coal Trade Association of this city, which opened for business on Dec. 9, proved satisfactory to the officers of the association. There were many inquiries and the trade appeared to be interested.

Current quotations, based on Government prices at the mines, net ton f.o.b., tidewater at the lower ports, are as follows:

	Mine Gross	F.o.b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite demand easing off. Mild weather continues. Better shipments. Administration modifies storing order. Cold weather needed to sustain individual prices. Stove and nut tight. Pea and egg quite free. Buckwheat only strong steam size. Bituminous unchanged. Good supply. Government prices still effective.

Anthracite—The trend of sentiment in regard to the local situation seems now to be running in one direction. The pessimists are gradually changing their views and now admit they were unduly disturbed. It is probable the unusually wild weather has done much to calm the fears of the seller as well as the buyer. Householders with a few tons in the cellars are certainly not showing the same anxiety to have their orders completed, and in most cases are accepting the assurance of their dealers that there is no cause for alarm.

The consignments to the city have not been unusually heavy, but they have been wisely distributed. The largest operating company's shipments have been most substantial. It was this trade that was becoming panicky, because it had been almost neglected for about six weeks. It is believed that before the first of the year the entire situation will be well in hand.

Dealers who have unfilled orders in the suburban and outlying districts have been informed by the local fuel administrator that they may deliver up to 100 per cent. on egg and pea sizes. He explains that this is to prevent any accumulation of these apparently free sizes and to keep equipment moving. However, where dealers have a stock of other sizes that warrant it, permission will be given to deliver these sizes up to 100 per cent. of orders on hand, when a written application is made for same. This latest ruling indicates better than anything else the sudden change in the situation, for it was only two weeks ago that the fuel administrator notified all dealers that they must not deliver 100 per cent. of any order previous to Jan. 1.

There has been considerable talk in trade circles as to the position of the retailer when business connections are only with the smaller operators and brokers, whose prices are 75c. and 90c. higher than the big companies. The thought seems to be that if the Federal Fuel Administration retains control until Apr. 1, these rates will remain effective, because after the strenuous efforts to gain this point the individual operator will hesitate to change his position. If the retail business falls off before Apr. 1, which is far from improbable, coal will be free and the dealers who handle individual coal are wondering how they will compete with the dealer who purchases his supply from the companies.

Stove and chestnut are still scarce and most yards are bare of both sizes. This is usually because shipments are delivered to the consumers' cellars as soon as received. While buyers have not been able to accumulate stocks of these sizes, yet we have come across two large dealers who had all sizes for sale, one of them going so far as to advertise the fact in his office window for an entire week. Egg is quite free, and it is probably only from the Germantown and Chestnut Hill sections that the demand is for a substantial tonnage. A number of dealers have held orders on this size with their shippers, and late in the week one of the large companies was finding this size to be quite a problem for it to handle. Pea too is easy, and a number of dealers advise us they have suspended shipments of it for a time. This size is sure to come into its own later in the season. One dealer who handles an enormous tonnage of this size, on account of his 1916 business, finds himself with an extra heavy tonnage now on hand and moving slow for this time of year. He explains that last year a large portion of his trade got so used to the larger sizes that they have found out the economy and convenience of their use despite the higher price and are now insisting on the larger sizes.

In the steam trade buckwheat is quite brisk and one house reports selling at $4.50 here, and 10c. higher in New York. Rice is weaker than buckwheat, but much stronger than barley or culm, which are flat. The piles of these latter in the storage yards of the big companies are mounting.

Bituminous—There is no particular change in the situation. Coal is fairly plentiful, especially the low grades. The good coals are all quickly taken. There has also been some increase in production, with the car supply about equal to production requirements. Some of the wagon mines are still able to get out a little tonnage by making use of flat cars, which is the only class of equipment they can get now.

BALTIMORE

Heavy movement of soft coal continues. More of better grades released on open market. Some sales below maximum. Big improvement in supply of anthracite promised.

Bituminous—With a general industrial supply of ample proportions and demand not overactive, the flow of coal from mines to this section is of such a nature as to require side-tracking at production points at times to prevent undue congestion at plants that can handle no more fuel for the present. The same conditions exist at the terminals here. Coal on demurrage for several days at a time has been noted here recently. This is striking, and shows the effect of the stoppage of war-order work in this and other nearby sections.

Georges Creek Tyson and other grades of more or less desirable nature are appearing on the market with increasing frequency. Some high-grade coals have also been released from pools that were until quite recently considered strictly Government distribution groups. The trade as a whole views with satisfaction the semi-official announcement from Washington that there has been abandonment of a plan of sudden cancellation of zoning orders and of all price regulation, and to substitute therefore a more gradual plan of release after business generally had settled down to post-war conditions. It is felt that this will prevent the overflow of higher grade coals into some sections where dealers and distributors are heavily stocked with inferior coal bought at full Government prices. Meanwhile there can be no doubt that coals are now offering here in some cases below the Government maximum. Some fuel, not those of best grade, have been offered here at anywhere from 15 to 40c. off the Government maximum.

Anthracite — The hard-coal situation shows signs of improvement. The mild winter so far has been a tremendous factor in easing the situation. The past week saw a considerable movement here, and much needed nut and some urgently needed stove coal came through. One of the largest producing companies, which was about 30 per cent. short of its usual annual movement to dealers here, also sent a promise that, now the New England and Northwestern movement had let up, it would attempt to make up the deficiency in the next thirty days or so.

The local fuel administration is planning, as soon as everyone has some coal in their cellars, to allow delivery of one-half of the one-third undelivered to most customers under the two-thirds delivery plan of the administration.

Lake Markets

PITTSBURGH

Production only slightly increased. Gas coal in demand. Market generally steady.

There has been only a slight further increase in coal production in the Pittsburgh district, but apart from gas coal the supplies have been sufficient to demand. There is no snap to the market, but if there are any actual price concessions they apply only to poorer and less desirable grades. Railroad requirements continue heavy. As usual, high-grade gas coal is in short supply for steel mills and gas works.

There has not been much rearrangement as yet in the distribution of coal to by-product coke ovens, although many switches are deisred by the coke producers in order to provide them with coal more suited to their work. In several instances Connellsville coal is sought in larger quantity, but supplies from that quarter are but slightly increased. When everything is working smoothly as to distribution, a large tonnage of Pittsburgh district coal will still be used for byproduct coking.

Many consumers are drawing upon stock piles as they are not seriously concerned as to the continuance of supplies during the winter and think there are considerable chance of the market's easing off. A report from Washington is that the Fuel Administration intends to end its work by Dec. 31, except as to anthracite, but it is not at all certain that the body will continue to function for the first three months of the new year.

The market remains quotable at Government limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district.

BUFFALO

More anthracite for the city. Too much bituminous everywhere. Jobbers confident. Restrictions going. Better tone all through the trade. Lakes closing.

Bituminous—Jobbers grow more confident every day. With the existence of a surplus of coal, operators are returning to them and old relations are being resumed. So much coal is in the hands of consumers that they are indifferent to the market, and buyers are no longer anxious over the supply. They purpose using up most of their coal before purchasing more, as coal can be had when wanted.

In the dropping of restrictions one after another, bituminous sellers see a chance to make their old April contracts again without any Government supervision. At the same time they do not like the idea of giving up the arbitrary price, for many of them think that if this is done before the supply on hand is reduced materially the price will decline. Operators are saying that they will shut down rather than stand low prices.

The situation in Canada has been serious to the shipper. Coal was piled in there till nobody could sell any, and there is a

surplus there yet. Even the munition plants that shut down offered their surplus coal on the market, and the situation was about as bad as it could be. The Canadian license to shippers has been dropped, which means that the authorities are no longer afraid that the supply will run short.

Anthracite—The change has come. The lakes are closing and coal is pouring into the city, sometimes faster than the retailers can handle it. Other points in the all-rail district hereabouts are also getting more coal. It appears that the New England demand has been pretty well satisfied, so that there is plenty for this section. Already the feeling is improved. One big factor in the situation is the weather.

The lake trade closes with all upper lake ports pretty well stocked up. There was a shortage in Milwaukee, but that has also been made up. Shipments for the week are mainly to Milwaukee, 66,300 tons; to Chicago, 12,500 tons, and to Duluth, 12,000 tons, a total of 90,800 tons. The final cargo is not reported, but the season is practically at an end, with shipments of 3,557,000 tons, as against 4,106,598 tons last season. The season has been prosperous; scarcely any losses on the lakes has been reported.

CLEVELAND

Some large steam-coal buyers stand ready to take fair-sized blocks of regular No. 8 at 25 to 35c. off the Government maximum, but this business so far has not proved attractive to operators. Stripping coal continues to be offered at marked reductions, while it is believed some No. 8 coal has failed to bring the top price. Anthracite receipts are beginning to increase.

Bituminous—In their efforts to move surplus stocks at the mines, several operators have come across a couple of large steam-coal users in northern Ohio who have made known their willingness to do business at a concession of 25 to 35c. from the Government schedule. These interests have not yet felt the curtailing effects of the signing of the armistice or have made the change from a war to a peace basis without a ripple. Consequently, not having added to their stock piles for about 30 days, their stocks are fast being depleted. Another 30 days will find them actively in the market, unless they place their business meanwhile. So far, it appears, no operator has been so pressed or has reached the state of mind where he is agreeable to breaking through the top of the market to this extent.

Barring a few spots where pessimism reigns unchecked, a feeling of optimism pervades the local market. Operators agree freely that every element entering into the situation is unfavorable. The lake trade is at an end. The mild weather has wrecked retail business, and stock piles abound everywhere. But, operators point out, another three months will see coal again moving toward lower lake ports. The industrial readjustment is being made with a great deal less flurry than anticipated, and unless business receives a severe check shortly, steam-coal users will be back in 30 to 45 days. If the trade can weather December and the beginning of January without a break, it is safe, in the opinion of many well informed operators. It is of this reasoning that the determination to shut down before shading is born. The market hinges entirely upon the ease with which the readjustment is made.

Despite insistent denials that any standard No. 8 coal has been sold below the Government price, the fact remains that more than one retail dealer claims to be able to locate a few small blocks at about 25c. off, a 25-cent reduction apparently representing the idea of buyers where the price list should take a fresh hold. Stripping coal is consistently offered at 50c. to $1 off the top price, with much offering and little taking. This action on the part of stripping operators is weakening—at least sentimentally—the position of standard No. 8 coal.

Production again is on the upgrade, and it is believed influenza has been conquered. The report of the Pittsburg Vein Operators' Association of Ohio for the week of Nov. 30 places shipments at 5264 cars, compared with 4742 cars the first week preceding and 4760 the second. Many mines in eastern and southern Ohio are being worked only half time, while several have been closed for several weeks—because of inability to market coal with labor and material costs so high, the mine workers have been pointedly told.

Anthracite—By paying a small independent $1.05 more a ton than the larger operators demand—of which 30c. represents commission—one retail dealer is able to get shipments of pea at the rate of five to six cars a week. This finds ready takers at a retail price of $10.35 a ton, delivered. The continued warm weather has virtually knocked the bottom out of retail consumption and the calls for anthracite have fallen off markedly.

DETROIT

Undistributed stocks in retailers' yards and large reserves in possession of steam-coal users curtail bituminous trade. Anthracite supply is short.

Bituminous—To the presence of too much bituminous coal in Detroit and the fact that considerable of it is stock of an inferior quality jobbers ascribe the present rather inactive condition of the local market. For some time past wholesalers and jobbers have found it difficult to book orders for further supplies.

In the case of many of the large consumers of steam coal, reserves seem to have been increased to unduly large proportions by the fear that the supply of coal might be cut off or made uncertain with the coming of winter. In their anxiety to escape perils of deficient supply, a number of buyers are said to have released orders to agents with apparent disregard of the total of the tonnage represented, until shipments began arriving. They contrived also to accumulate considerable of the coal sent into Detroit by the fuel administration from mines in Illinois and Indiana.

Because of the more-than-sufficient reserves built up through these activities dealers find the steam-coal users are not now in receptive mood, though the jobbers are again able to supply the more desirable grades of coal from West Virginia and Ohio. These for a time had been withheld from the steam plants.

Te retail dealers also are overstocked with bituminous coal, while the weather of the last six weeks has not been sufficiently severe to create an incentive for buying among their customers. The domestic consumers also are showing an inclination to discriminate in favor of coal of a better grade or in more desirable form than the stock many of the retailers are able to supply. The City of Detroit has been asked to assist the retailers by taking over some 25,000 tons of the excess stock.

Anthracite—Supplies of anthracite in the yards of nearly all dealers are low, while the small volume of receipts scarcely meets the requirements of the classes of concumers that, under the fuel administration regulations, are permitted priority of supply. Were weather conditions to become severely cold, dealers would be besieged with calls for anthracite which they could not provide.

COLUMBUS

The coal trade continues quiet in every way. Steam demand is small and domestic trade is also reduced to a minimum because of continued warm weather. Prices are not demoralized, although some cutting is reported. The tone of the trade is not good.

The coal trade is now "marking time," so to speak, until readjustment is started and until reserve stocks on hand are used up. As a result there is little demand for any grae of coal and production has been reduced. Coal men in all departments of the industry believe that present conditions are only temporary, and that there will be a much better demand after the first of the year. Steam trade is quiet, as surplus stocks in the hands of consumers are extra large. Purchasing agents are loath to increase their fuel stocks until the trend of affairs is seen. Many plants have fuel stocks to last for three to five months and additional orders are out of the question. The smaller consumers are not worrying about their stocks, believing that they can buy at any time. Railroads are not taking any large amount and that is cutting into the volume. Steam prices are being shaded, but it is realized that orders can not be secured by cutting, as the buying public do not want the coal at any price.

The domestic trade is also quiet, due largely to the continued warm weather. The season so far has been very unfavorable for the retail trade. About 75 per cent. of the users have their winters fuel on hand, and it will require a cold spell to bring the remainder in the market. Rural dealers are buying to a certain extent, as their customers are not as well stocked as city residents. Retail prices are steady at former levels and there is no general disposition to shade quotations. The differential between thick and thin vein Hocking has been removed, however.

CINCINNATI

Extremely mild weather continues to dominate market, while industrial uncertainty also holds down demand. Shipments are satisfactory, in view of this situation.

The continuation of extraordinarily mild weather has kept the demand for fuel down to a very low point, considering the lateness of the season, as domestic consumers have not been forced into the market to the extent which is usually the case at this time of the year, especially with the high average of stored coal on hand. When it is considered, in connection with this quiet state of the domestic market, that the steam side of the market is equally quiet, or more so, it can be seen that the trade, rather to its surprise, is facing an unusually dull period.

The decided uncertainty of all branches of manufacturing as to the future, and the quandary in particular of those numerous industries which have for several years past been engaged almost wholly on war work, makes for cautious buying on their part, and also accounts for very limited needs by them. Many plants, in fact, have virtually nothing to do just now, and will have little to do until business has had a chance to adjust itself to peace, and peace demands have an opportunity to make themselves felt, which it is hardly expected will happen in less than several months.

The recurrence of the influenza epidemic, after it was thought to be on the wane, is also having its effect on business, both at the mines and among industrial consumers of coal. While the disease seems to be less virulent, judging by the proportion of fatalities, the number of cases is alarmingly large, and is hampering industry seriously. In spite of this continued handicap at the mines, however, production measures well up to the limited requirements of the trade, on account of the conditions named.

LOUISVILLE

Demand for all grades draggy and poor. Producers and jobbers making a hard drive for business. Retailers waiting for telephones to ring, and trying to collect old accounts.

December half gone and no business coming and none in sight, appears to be the situation in Louisville. Kentucky operators, eastern, western and southeastern, are all trying hard enough to land business, and their selling organizations are working overtime. However, there is very little industrial demand, while domestic demand is at a standstill as the weather has been so mild that the really poor man hasn't had to start a fire as yet. Western Kentucky nut and slack, also thin screenings, are being sold at considerably under the market. Prices show much weakness, although locally the trade is making a hard drive to hold up Government prices in a retail way.

It is doubtful whether a similar situation to that now existing has ever been known at this time of year in the coal trade, as the bottom has dropped completely out from under the demand, and it is merely a question of whether the market will shoot to pieces.

BIRMINGHAM

Inquiry brisk for both steam and domestic coal. Supply of both grades short of requirements. Production now badly crippled; will likely show little improvement until after holidays and subsidence of influenza.

There is a sharp and strong demand in the local market from all classes of steam users, and inquiries have been more plentiful and insistent the past week than for quite a while. Industrial plants, public utilities, railroads and furnace companies are reported as active in the buying movement. Undoubtedly the trade is stimulated by the approach of the holidays and the desire of users to stock up for the idle period at the mines, and the demand is further strengthened by the depletion of stocks in the hands of consumers some weeks ago, due to current receipts not being sufficient in some time to avoid resorting to the stock pile. Domestic coal is specially scarce, while the demand is strong and incessant.

Coal mining in Alabama is suffering seriously from a second visitation of the influenza, and there is so much sickness among the mine workers and their families that operations are badly handicapped and the output fell to 322,591 tons for the week ending Nov. 30, or a loss of about 36,000 tons compared with the previous like period. Little betterment in production can be expected until after the holidays.

Coke

CONNELLSVILLE

Coke still scarce. Furnaces concerned over possibility of early removal of Government control.

Production of coke in the Connellsville region has increased, but only slightly, and blast furnaces are feeling the effects of the reduced output that has now obtained for several weeks. While few furnaces are

banked, many are operating with reduced blast pressures so as to cut down the consumption of coke. While the epidemic of influenza is charged with the reduced output of coke, the disease is much less prevalent and output would probably be larger if the men were more anxious to work. Operators are not encouraging them as formerly, and seem to regard the curtailment in output as very far from an unmixed evil by reason of its tending to support the market.

The quality of coke being made is decidedly improved as a result of the inspection system now in operation, whereby inspectors of the furnaces scrutinize coke before shipment.

Blast furnaces are much concerned over the possibility of the Fuel Administration relinquishing its control of coke prices Dec. 31. They fear a sharp advance in the market if this is done, as coke is decidedly scarce and indeed is generally scarce at holiday time. Pig iron prices are marked for a $3 decline, in line with the recommenations the general committee of the American Iron and Steel Institute had prepared for submission last week to the War Industries Board, to make a price basis for the first quarter of the new year. While the War Industries Board refused to consider the matter, as it is relinquishing price control, the iron and steel producers will probably act on the schedule of price reductions just the same. With a $3 decline in pig iron, furnacemen think they should have a lower price for coke. Many coke contracts have been made for the first half or all of next year. Some of these call for adjustment at the open market price in case Government control is taken off, but others provide that in such case the last Government price shall apply. Furnaces holding such contracts would therefore like to see the Fuel Administration reduce its price limit before it ceases functioning.

The market is quotable at Government limits, as follows: Furnace, $6; foundry, 72-hour selected, $7; crushed, over ¾-in., $7.30; clean screenings, over ½-in., $5.50, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Dec. 7 at 272,750 tons, an increase of 16,035 tons, and raw coal shipped at 194,091 tons, an increase of 2053 tons.

Buffalo—The scarcity still continues. All the furnaces in this territory, even those with byproduct plants of their own and commonly making a surplus, are asking for coke of the beehive producers. The shortage is not likely to last, as the labor shortage that has caused it is not expected to last. It appears that the demand for iron is to keep up, so the coke market ought to remain strong. Fuel coke is firm where it competes with anthracite, but not otherwise. Receipts of iron ore to December were 8,663,400 gross tons, as compared with 7,438,533 to the same time last season. A little will still come in this month.

Middle Western

GENERAL REVIEW

Market as weak as ever on all grades of bituminous. Too much coal is being produced for current needs. Talk of curtailing production to keep prices at Government maximum.

The coal market in this territory is uniformly weak, and will continue so for at least the next month or two. There has never been a time in the history of coal production in Illinois or Indiana when the production has been so large and the demand so small. Today, the market is weak on all bituminous coal, all grades and sizes, and the demand is lessening from week to week. It appears that every consumer of coal, factory or retailer, has more than enough fuel on hand for current needs.

It is well known that for the past month or so the mines of Illinois and Indiana have been producing much more coal than the zones allowed them can absorb. Some of the producers of the "weak sister" type have tried to force coal on the consumer by the price-cutting method. At first this means of obtaining orders met with some success, but after a short time it failed to prove effective.

It was also shown in a number of instances that the operator who remained firm and sold his coal strictly on a basis of "Government price current at time of shipment" had just as much business as the producer with cold feet who rushed out into the market and tried to sell his coal at a discount. It has been pretty conclusively proved, of late, that if the average buyer of coal is in the market, he is willing to pay the Government price for his coal. He knows that the Fuel Administration has set a fair margin of profit on coal, and nine times out of ten he is willing to pay it.

The long and short of the present situation, or dilemma, rather, in this part of the United States is that too much coal is being produced. If any sort of order is to be maintained in the market, and in the coal industry, it will be absolutely necessary for the operators to curtail production. The object of shutting off on production would not be to increase prices, which is impossible, as they are controlled by the Fuel Administration, but to keep the operators from becoming demoralized through reckless price cutting and competition.

As a matter of fact the public have on hand today more coal than their immediate needs require, and in view of the fact that this coal was purchased earlier in the season, at full Government price, it will not help the standing of the coal industry with the public to offer coal now at substantial discounts from the various prices set by the Fuel Administration.

The resignation of Dr. Garfield came as a distinct surprise to the majority of the coal trade here, and the news of his withdrawal lent an additional element of uncertainty to the market. The coal industry in the Middle West, practically as a unit, very much regret Dr. Garfield's resignation, as he has won the entire confidence and well wishes of the coal-producing industry as represented by the operators of Illinois and Indiana.

CHICAGO

No demand for either steam or domestic. Removal of zone restrictions not favored by Mid West operators.

There is practically no demand in the city for steam coal, and no demand whatsoever for domestic coal. The Fuel Administration a short time back published a statement to the effect that they were considering abolishing all zone and price restrictions, to become effective Dec. 15. If such a step is taken, it will seriously affect the retail dealers of Chicago as well as a number of operators producing the better grade Illinois and Indiana coals. The retail dealers will be hurt because it will mean they will be kept with a big stock of unsold Illinois and Indiana coals on hand that will be exceedingly difficult to move, and the operators will suffer because they will lose a tremendous tonnage in Chicago, which will revert once more to the higher grade Eastern coals.

Raymond E. Durham, the United States Fuel Administrator for Illinois, has written to Washington and requested that the present coal zones be maintained, at least until next spring. He has asked in addition that at least six or eight weeks' notice be given before the zones are abolished, in order to give the industry a chance to adjust itself to changed conditions.

MILWAUKEE

Unusually mild weather makes the coal market slow. Liberal receipts of anthracite during the closing days of lake navigation. Situation considered satisfactory.

The coal market is dull and lacks the nervous tension which has characterized it at this time of the year since war conditions brought about restrictions in movement and price. There seems to be a feeling that there will be coal enough on hand when the last vessel is docked to meet all wants during the coming winter. The hard coal supply will necessarily have to be supplemented by rail, but the docks are loaded with bituminous coal. Soft coal is not in brisk demand on account of the extremely mild weather and also because many consumers in the city and interior who formerly were sure of getting their supplies during the winter as needed, have safeguarded their interests by accumulating stock piles by rail during the summer. The dockmen are pressing their holdings on the market, but as yet prices have not been shaded.

The movement of coal by lake to this port thus far in December has been very liberal as far as anthracite is concerned, and Fuel Administrator Fitzgerald holds that when the season closes Milwaukee will have received her full quota of hard coal. Within two weeks 160,000 tons of coal for Lake Superior and 140,000 tons for Lake Michigan have been shipped from lower lake ports. Two large cargoes of anthracite are still to arrive here. Some soft coal cargoes will probably be allowed to remain afloat until there is more room on the docks.

Thus far in December eleven cargoes of hard coal aggregating 87,817 tons have been received. During the same period 29,500 tons of bituminous coal have arrived. Lake receipts of anthracite will show a falling off for the season of approximately 140,000 tons, while bituminous coal will show a gain of about 400,000 tons. Receipts by carferry and by rail were both heavier than last year throughout most of the season.

Soft coal piles seem to develop spontaneous combustion to a greater extent than usual this year. In addition to smoldering fires in dock yards, the partial destruction of two school buildings is attributed to ignition of coal in the bins.

ST. LOUIS

The market continues inactive, with no demand for domestic or steam. Most unusually mild weather thus far and demoralized conditions have broken all precedents.

Continued mild weather keeps the local market in a most unsatisfactory condition. This is the first winter in nineteen years that has been so open and so mild. Anticipating weather somewhat on the order of a year ago, everybody stocked up with coal; and now, in many intances, there are days that fuel is really not essential for heating. Storage piles are catching fire, and this to some extent is forcing the use of this coal at once, but in other places the users are preferably burning their storage coal rather than buy on the market. This has a tendency to bring the prices down. The present figures, however, are as low as coal can be sold with profit, and in many instances it is a case of selling it at actual cost as far as Standard coal is concerned.

The amount of this coal moving into St. Louis at the present time is almost nothing for domestic and very little for steam. Fortunately the railroads came in the past week and bought considerable coal, and they as good as made their own price. This is helping conditions in the Standard field wonderfully, but how long it will continue is a question. Many mines are shutting down and work only one or two days a week, and those that are trying to work have unbilled coal every night.

There seems to be a little unrest among the miners. Their income is not as great as it used to be, and they figure that they ought to get a little more money out of the coal that is put on the market.

Conditions in the Mt. Olive field are somewhat better than those in the Standard field. The mines here seem to have better running time. Coal is moving north, with a fairly good railroad tonnage to help. Cars are plentiful and there is nothing in particular to worry the operators in this field, only, of course, that they have not got as much business as they would like to have. They have idle days on account of no orders.

In the Duquoin and Carterville fields it is apparent that operators are catching up with their orders. Several mines now have unbilled coal at night, and were it not for railroad business in this field many mines would be idle on account of no business. Car supply has not been as good in the past week as heretofore, and the movement is slowing up a little. In general conditions are satisfactory. Prices are being pretty well maintained in this field, whereas they are breaking in the other fields. In the St. Louis market Standard 2-in. lump is going as low as $1.75 to $1.85 and $1.90, the mine-run $1.60 to $1.65, and screenings about $1.40. Six-inch lump is going from $2 to $2.25, depending upon the quality.

Mt. Olive coal can be bought as low as $2.40 for the domestic sizes, and here and there is a break in the Carterville price to $2.40; but this is not general and was likely made on equipment that was restricted.

No Arkansas coals are coming in and there is no indication that anything from the east will come in for many months to come. There are about 80,000 tons of storage coal in the dealers' bins in St. Louis, and it is estimated that manufacturing plants here have 100,000 to 120,000 tons in reserve.

It is almost impossible to move local coke, and the fuel situation is not a satisfactory one from any viewpoint.

The Government maximum price here, with the exceptions above noted, is:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.75	$2.55@2.75	$2.40@2.70
3x6-in. egg	2.55@2.75	2.55@2.75	2.40@2.70
2x3-in. nut	2.55@2.75	2.55@2.75	2.40@2.70
Washed:			
No. 1	3.05@3.20	3.05@3.20	.....
No. 2	3.05@3.20	3.05@3.20	.....
No. 3	3.05@3.20	3.05@3.20	.....
Mine Run	2.35@2.50	2.35@2.50	2.20@2.30
Screenings	2.17@2.32	2.17@1.32	1.50@1.60

Special preparation on Carterville is 10 cents extra.
Williamson & Franklin Co. rate is $1.10.
Other fields 95 cents.

COAL AGE

Volume 14 New York, December 26, 1918 Number 26

THE NEW YEAR

By FLOYD W. PARSONS

"I'm mighty glad to see you, Miss Liberty, and I don't deny you are the grandest lady on earth; but if you ever want to see me again, you'll have to turn around and face the other way."

Such was the comment of a soldier boy standing beside me on the deck of a steamer entering New York harbor the other day. The same thought was current in the minds of hundreds of other Americans returning from "over there."

If the war has done nothing else, it has caused several million Yankees to appreciate more properly this great land of freedom. Most of our soldiers will return home minus any desire to again cross the Atlantic. The horrors of this conflict in Europe have left an impression on human hearts that will not be effaced for generations. The boys will come back with a far deeper appreciation of law, order and justice. They will take good care that no elements of discontent in our population employ violence in their effort to realize radical aspirations.

Our returning soldiers know now how great is the waste and sorrow of war. They have learned that peace must be founded on high principles and be supported by great virtues; that deeds are silent, and that people who boast most generally fail most; that one affliction is better than a thousand exhortations; that it is easier to tear down than to build up; and that one may as well look for ground where no weed will thrive as for a human heart where no error will grow.

No benefits can ever justify war, but our losses and sacrifices have made the United States a nobler nation, a nation with an awakened conscience. The chief danger is that we may backslide. Nothing could be worse than for America to fail in her effort to champion the cause of oppressed peoples. The world would be set back beyond redemption, and the last embers of hope would die in the breast of civilized humanity.

We start the New Year with problems that have never before confronted us. Thousands of soldiers are returning to find industrial employment at a moment when our National pursuit ceases to be the business of making war. At the same time our promises must be kept, and we are obligated to feed millions of mouths in Europe. Consequently, food may be dear and employment slack during the early days of our reconstruction era.

Our duty is plain. Each individual must resolve to serve and save as never before. The end of the struggle spells the beginning of greater sacrifices. During the days of war prosperity, the average American workman has not let go the bridle. In the coming months of business readjustment the things that will count are caution and patience. We must do head work before hand work, and not forget that the edge of the shovel and the point of the plow are close kin to the meal-bag.

We might as well try to improve the rainbow by adding another hue as to expect that the wheels of industry will move without the force of our daily labor. The law of supply and demand will still be on the job 24 hours each day. As in times past fortune will smile on the fellow who conserves his time, grins at bad luck, exercises patience and discretion, and keeps everlastingly at it.

If there ever were a time for high resolves, it is right now, during these days of world convulsion. Let us stop theorizing and commence the New Year by settling on a course of old-fashioned, honest hustle, which alone has made America the grandest and the most prosperous land that lies under the sun.

The Consolidation Coal Company

BY GEORGE W. HARRIS
Editorial Staff *Coal Age*

FIFTEEN million tons of bituminous coal is a big annual shipment of fuel. The total estimated requirements of bituminous coal of the whole country for the current year is only about 42 times this amount. The only company exceeding a shipment of this magnitude and kind of coal—the Pittsburgh Coal Co.—loaded 18,709,926 tons for transportation in 1916, its year of highest production. The subsidiary companies of the United States Steel Corporation manufacturing beehive coke have mined an amount exceeding the Pittsburgh company's record, but they made the greater part of this tonnage into coke.

These achievements are cited principally to show the importance of a concern aspiring to a 15 million annual tonnage. The Consolidation Coal Co., with mines in four states, produced about 10¾ million tons of coal in 1915, its year of greatest output. During the first part of the present year, this company hoped to reach a tonnage somewhere near the capacity of its mines, but on account of shortage of railroad cars and labor, and lately the influenza epidemic in addition, its expectations will not be fulfilled—all these causes have contributed to a curtailment of production.

FIG. 1. STEEL TIPPLE UNDER CONSTRUCTION AT MINE NO. 87

The burning question is one of lack of railroad cars, and this situation has been aggravated by the advent of many small mines. There was practically no such thing as wagon mines in the Fairmont region before the war; now there are over 100 such mines operating in this region alone—they cannot load rail coal direct. In the last three years 90 per cent. of the wagon mines in this territory started up; there are said to be none in eastern Kentucky, but there are quite a few in the Maryland and Pennsylvania divisions of the Consolidation company. These small mines seem to increase the tonnage shipped, on first thought; but an analysis of the situation shows that less railroad coal is sent to market on account of the interference of these wagon mines.

The proposition is as follows: A small mine opens up and is given one car a day to load by the railroad company; if this car is loaded on time one car a day is allowed regularly to the mine—there is no demurrage in any event. Should the mine prove to have a capacity to load more cars, then they are supplied up to four in number daily. At this point it generally operates that greater tonnage is only secured by a siding or branch line being put in from the railroad, in which case the mine becomes a commercial shipping mine. Under this classification a railroad official rates the mine regularly as to its capacity to load coal, noting the various phases of its development and its equipment for handling coal from mine face to railroad car. Cars are distributed among the various operations along the line of the road, according to this annual rating.

Returning to the loading of coal by the wagon mines: Each mine receives a car a day and a time limit of two days is placed on its loading. Should it take two days to load this car, note is made of the fact on a list of such mines and the mine does not get another empty car until every other mine on the list is given one. In this extreme case at least 12 hours are saved on the part of the commercial mines; here cars placed in the morning are loaded and ready to be taken out not later than the next night. Furthermore, the large shipper is a simpler proposition for the railroad people; the cars to be handled are more concentrated, time is saved in making up trains and track arrangements are less complicated. There is no comparison between the efficiency of the small mine with its hand labor and the big plant equipped with modern machinery for handling coal. The small mines absorb many laborers working at comparatively low efficiency at a time when every man should count. The large producers often have been handicapped by shortage of labor and poor transportation from making the proper use of their equipment, which represents a large investment.

A further thought suggests itself in connection with the small mines. Operators and miners have been working to the limit to produce coal. However, the time

FIG. 2. BIRDSEYE VIEW OF MINE NO. 87

may come when changed market conditions will cause a return approaching the old competitive state of affairs. In that event what will be the fate of the small mine poorly equipped to mine coal in competition with the big plants? In the aggregate these small investments represent a significant sum which might have found better application at the time made and may constitute a considerable loss in the future. Advocates of directed expansion of the development of the country's resources might find an illustration of wasted effort in many of these small mines.

In 1915 the Consolidation Coal Co. shipped about 37 per cent. of the total production of Marion and Harrison Counties, West Virginia, for that year, and that performance holds good up to the present time. The location of the mines of this company in the Fairmont-Clarksburg region is shown in Fig. 4. In this section there are some fifty Consolidation mines, three-fifths of them, or the older plants, being on the main line between Fairmont and Clarksburg; the remainder and later operations are mainly on short branches. From this region comes half of the total tonnage of the company; about one-quarter of its annual coal shipment is produced in the Elkhorn, Ky., field and the balance mainly from the Somerset, Penn., and Georges Creek, Md., divisions.

This company began shipping coal in 1864, when it mined 37,678 tons from the Georges Creek operations; shipments increased from this region until in 1900 they amounted to 1,299,374 tons of coal. In 1901 the Fairmont Coal Co. was acquired by the Consolidation, which gave the combination an additional tonnage of about 2½ million; the following year the production of the Fairmont properties was doubled. The Somerset Coal Co. was purchased in 1902, and the mines of this company located in Pennsylvania contributed around 1½ million additional tons of coal. The Millers Creek and Elkhorn regions of Kentucky were opened up by the company in 1911 and 1912 respectively; the former contributes about half a million and the latter some two million tons of coal annually. The aggregate tonnage from all these mines was 11,722,384 tons in 1915, the year of greatest production of this company. Bare statistics are generally dry reading, but an additional fact, the total production of the company from 1864 to the end of 1917—188,054,220 tons—would be an impressive statement at any time, more especially so during times of great demand for fuel.

A coal man can hardly fail to find much that is of interest in the 54th annual report of the Consolidation Coal Co. Under "Capital Assets," coal land and other real estate are valued at $83,651,146 in round figures; deducting $9,019,472 as reserve for exhaustion, there remains $74,631,674. Under "Mining Plants and Equipment" there are a number of matters of especial interest; accordingly the main items of this account are given in the accompanying table under that head. The remaining or less important items are grouped under "Other Plant and Equipment." (See table I).

In the inventory of Consolidation plant and equipment, the most prominent item is "Mine Openings and Gradings"—a sum exceeding five million dollars is invested in underground development. This is an improvement which cannot be made available at short

FIG. 3. TYPICAL MINERS' HOMES—PENNSYLVANIA DIVISION OF CONSOLIDATION COAL COMPANY

notice—it takes time to drive entries, grade haulage roads and open up territory. If such improvements (narrow work) are kept well in advance of roomwork, the productive capacity of the mine can be greatly and quickly increased, which means more cars to load at the tipple. Steel rails represent a large investment to an operation, in this case considerably over 1½ million dollars. Heavy rails on main haulage roads tie up large sums but prove an extremely good investment. Nearly a million dollars is represented in the case of tipples and an equal sum in mine cars. This company at present is engaged in some extensive improvements, over

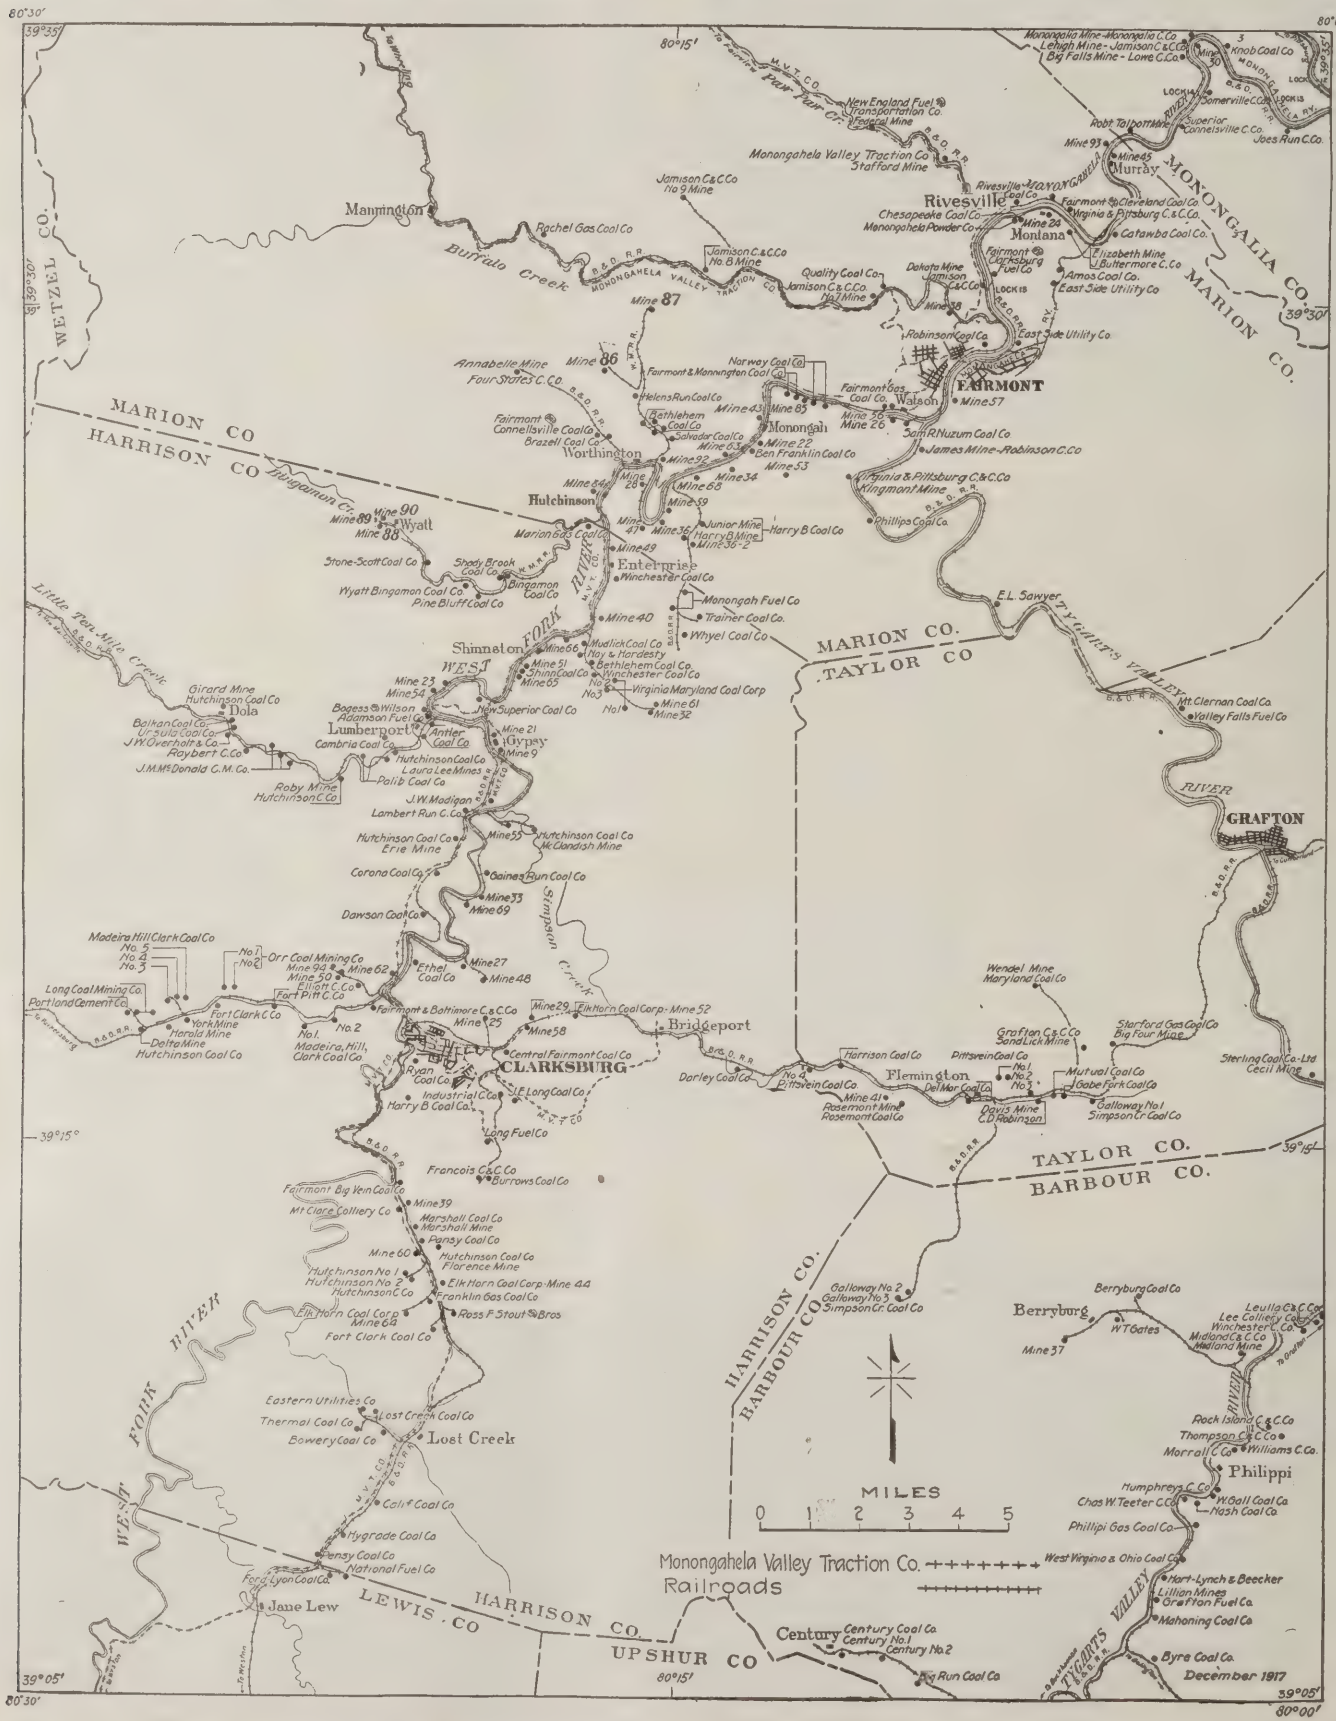


FIG. 4. LOCATION OF CONSOLIDATION MINES IN FAIRMONT REGION OF WEST VIRGINIA
Consolidation mines are indicated by number—as Mine 86

two million dollars being assigned to new work (not completed) in the West Virginia division and something over half this amount to the Pennsylvania division. In West Virginia some fine modern plants are under way. Mines Nos. 86 and 87, on a branch from the main line and about seven miles due west from Fairmont, are about completed. A view of the steel tipple at No. 87 taken while under construction is shown in Fig. 1. A later view of this plant (a shaft proposition) is shown in Fig. 2. On another branch at Wyatt (seven miles southwest of mines Nos. 86 and 87) is another big plant under development. Here three drift mines, Nos. 88, 89 and 90, will send coal to one tipple for preparation.

The various items entering into haulage—locomotives, trolley wire and equipment—represent another million dollars; mining machines are charged up at over half a million and power plants, substation and equipment at two million more. The electric end of the Consolidation equipment is valued at nearly four million dollars. An equal amount has been expended on tenement houses. Miners' houses, or "homes" as they should be termed in the case of this company, are shown in Fig. 3. This is a typical mining village of the better class.

The setting given the scene by the background of trees and the trees among the houses have considerably more than an artistic value. In the case of many towns and municipalities throughout the country officers or commissions are maintained to look after the trees to protect them from injury and replace them when necessary. Many times when a mining town is laid out with no more expense for shade than the care of existing trees, abundant shade can be secured which will add greatly to the comfort and pleasure of future occupants of the houses of such towns. This idea seems to have been followed in the case of the village illustrated.

A further illustration is afforded in the view given in Fig. 7 of the benefit of preserving natural beauties about the sites of homes and other buildings. This company has gone to considerable expense in developing the new Elkhorn, Ky., field to provide many advantages for its employees. This section is remote from large towns, and many of the privileges enjoyed by those living in or near municipalities can be participated in by not only the Elkhorn but also the employees of the company in other divisions as well. The company's statement referred to previously shows that over one hundred thousand dollars have been expended in recreation and amusement buildings and equipment alone. The amount spent in town improvement is not brought out as a distinct item.

FIG. 5. GROUP OF MINERS AT CONSOLIDATION COAL COMPANY OPERATION

Many nationalities and diverse elements are represented in the typical group of miners shown in Fig. 5. These men were photographed at the entrance to Mine No. 36, in the Fairmont region of West Virginia. If the capacity of a boiler plant can be judged by the amount of fuel fed to it, then some of these workers should be quantity coal loaders, judging from the size of the dinner pails carried, supplemented by other indications of huskiness. These men surely do not come out of the mine at noon when they can load coal.

It is to be regretted that the mines in northern West Virginia have no better transportation service to move coal from the tipple to market. At present the region is on a little better than half-time work. Some ten to eleven hundred railroad cars furnish daily transportation to eastern points; of this tonnage part goes via Connellsville over the Western Maryland. President J. H. Wheelwright of the company stated that the tonnage output for 1917 was over 1½ million tons less than for

TABLE I. MINING PLANTS AND EQUIPMENT

Mine openings and gradings	$5,240,407
Tipples and equipment	947,007

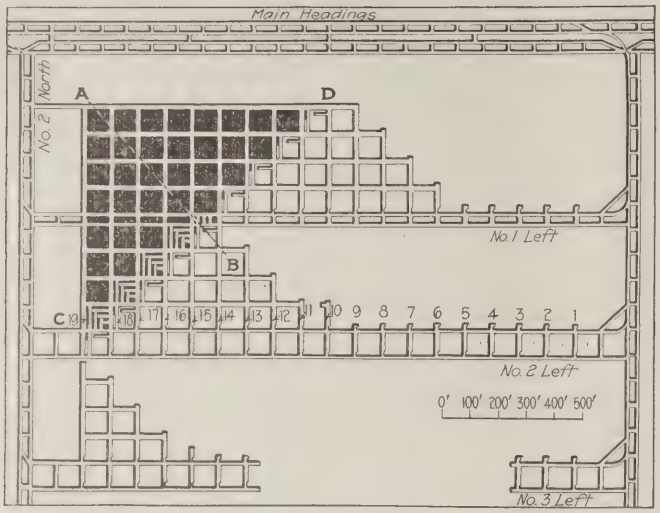

FIG. 6. GENERAL PLAN OF BLOCK SYSTEM OF MINING USED BY CONSOLIDATION COAL COMPANY

the preceding year. That this reduction in the production was caused by the failure of the railroad companies to furnish necessary transportation, which was very disappointing, especially in view of the large expenditures which had been made in opening and equipping new mines, and for additions and betterments in the extension of mines already in operation.

Prominent among the changes made by the Consolidation in betterments and methods at its mines is the adoption of the room-and-pillar panel method of mining on the block system. C. H. Tarleton, the manager of the West Virginia division of the company, is closely identified with this method as used today and states that it has the following pronounced advantages: (1) Absolute protection against squeeze and creep. (2) Greater safety to the miner while extracting pillar coal. (3) More economy in haulage, including track used; also economy in timber. (4) It permits of a more flexible method of removing or mining pillars. A comprehensive general plan of this method is shown in Fig. 6 and in detail in Fig. 8. Here the rooms are turned on 100-ft. centers and are driven 16 ft. wide and 400 ft. long from butt entries; rooms are connected every 100 ft. of advance by crosscuts which leave roof supports 80 ft. square. Never less than two pairs of butt entries are included in a panel, and where it is possible the panel is extended to cover three or four pairs of butts. The larger number of butt entries is preferred, as it is difficult to recover the barrier pillars left between panels as the coal is drawn from adjacent pillars down to it.

The block system permits of concentration of pillar work, which is well kept up as the rooms advance economically and safely. One of the greatest mistakes in mining is made by not removing pillars in time. Many cases could be cited of mines where cross or butt entries were driven to the limit before a single pillar was drawn on a pair of entries; this being true when rooms where turned and worked on a half to a mile of entry before robbing of the pillars commenced. This was supposed to be necessary in order to begin robbing at the room pillar next to the face of the entry. This plan has so many well known disadvantages as to need no special comment. A squeeze may develop where pillars stand for a year or so; top rock falling buries track unless it is removed in time; timber deteriorates, and so on. In the plan noted in Fig. 6, robbing of pillars commences as soon as a room is driven to the limit; the break in the top rock follows a diagonal line across the rooms where the work is carried out systematically.

In mining by the block system little timber is used in advancing. The track is carried along the rib which will be first extracted, and one row of props is placed on the other side; in a wider room two or three rows of props would be used. Refuse is stored in space which will never have to be used for other purposes. When a room is finished the pillar block nearest the face is attacked and robbing proceeds as indicated on the detail map, Fig. 8. This plan does not show different blocks in relation to each other, but illustrates the same 80-ft. block at different stages of working. With this plan the amount of work on the face of the coal should be about 57 per cent., the amount of solid work in each block about 72 per cent. and the amount of pillar work 28 per cent.

In this plan of robbing 13-ft. openings are driven in the block from two points and the 7-ft. strips of coal next to the gob are recovered as noted; these narrow strips of coal are shown hatched when they are drawn. In case gas is encountered it is simply necessary to use a little canvas, the same as in any other method. In the room-and-pillar work steel ties and light rails are

FIG. 7. EMPLOYEES' CLUB AND OFFICIALS' HOMES AT JENKINS, IN THE ELKHORN (KY.) DIVISION OF THE CONSOLIDATION COAL COMPANY

used; this constitutes flexible track and one easily laid by the miner. The timber used while robbing progresses is saved where practicable. The Sylat mechanical post puller manufactured by W. Sylvester, Parkersburg, W. Va., is used for recovering props, and it is also found handy to get cars on the track again; it is also used in the shop on car work.

A special modification of the method of robbing described has been found to greatly facilitate the drawing both of the barrier pillars between the panels and also the room stumps. The fracture of the top works out better and the work is more concentrated in the case of this modified method. Mr. Tarleton states in explanation of this matter that instead of the roof break following the line *CBD*, Fig. 6, the blocks are attacked so that the roof fracture follows the line *CBA* in robbing. In general in the Pittsburgh seam it is often stated that about 95 per cent. of the coal is recovered,

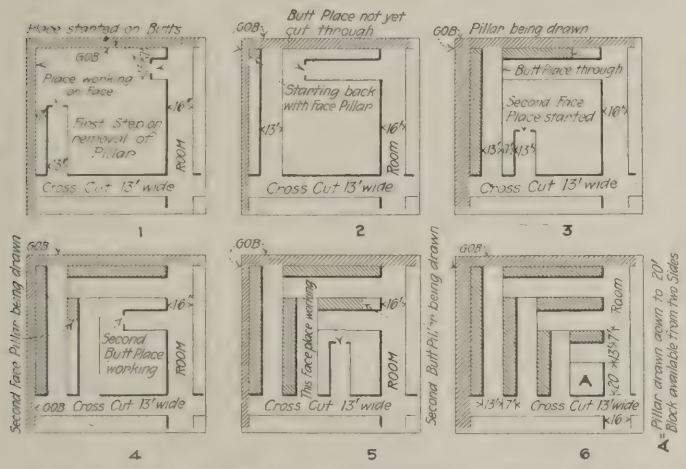

FIG. 8. DETAIL PLAN OF WORKING 80-FOOT BLOCK SYSTEM OF MINING

but some authorities who have given the matter considerable attention question whether such a high percentage of extraction is possible. It is thought by some that 85 per cent. recovery of coal is a more reasonable and practicable estimate. This is in view of the nature of the occurrence of the Pittsburgh seam; it is not all good coal to start with. There is usually a drawslate top over the main part of the seam; above this slate is a varying amount of coal of questionable value. Accordingly it is customary, where the drawslate tends to give trouble, to leave up from 4 to 8 in. of coal at a well defined parting to serve as a roof. In addition to the loss of much of this top coal, sometimes a slab of coal has to be left to hold back the gob in the robbed-out area. In view of all this, 85 per cent. is thought to be the actual amount of coal recovered.

The Consolidation Coal Co. has attained prominence not alone by virtue of the size of its annual shipments but by the excellence of the several products of its mines as well. The coals shipped to market by this company are the following well known fuels: The Georges Creek "Big Vein Cumberland," from Maryland; the Fairmont gas, locomotive and domestic, of northern West Virginia; the Millers Creek block and the Elkhorn coking, byproduct and gas coals of Kentucky, and the Somerset smokeless steam coals of Pennsylvania. These fuels took the highest award—the gold medal of honor—at the Panama-Pacific exposition.

The operating headquarters of this company is at Fairmont, W. Va., and executive offices at Baltimore, Md.; division offices are maintained at Fairmont, Frostburg, Md., Somerset, Penn., and at Jenkins and Van Lear, Ky. Sales offices have been established at Baltimore, New York, Philadelphia, Boston, Washington, Chicago, St. Louis, Detroit, Cincinnati, Louisville and Cumberland, and foreign offices at London and Genoa. The company has a controlling interest in the Northwestern Fuel Co., of St. Paul, Minn., the Metropolitan Coal Co. of Boston, and the Consolidation Coastwise Co., the last named corporation operating steamers and barges between ports on the Atlantic coast.

Anthracite Shipments in November

The effect of the influenza epidemic in the anthracite region is shown in the decrease of more than a million tons in the shipments for November compared with the preceding month, as reported to the Anthracite Bureau of Information in Philadelphia.

The shipments during November amounted to 5,276,659 tons as compared with 6,286,366 tons in October, a decrease of approximately 1,010,000 tons. As compared with shipments during November, 1917, which amounted to 6,545,313 tons, the shipments last month show a decrease of 1,268,654 tons. Shipments last month were the smallest since February, 1917.

Conditions in the region have been much improved since December came in, the force of the epidemic having largely spent itself; but in addition to this there has been an increase in the supply of labor due to the return of men from the service and other occupations.

The shipments by companies were as follows:

	November, 1918	November, 1917	Coal Year, 1918	Coal Year, 1917
P. & R. Ry	1,137,170	1,329,259	10,248,539	10,317,398
L. V. R.R.	973,865	1,158,158	9,884,413	9,844,000
C. R.R. of N. J.	450,360	557,090	4,626,285	4,698,230

L. & N. E. R.R.	271,504	362,202	2,624,316	2,827,941
Total	5,276,659	6,545,313	52,186,416	53,326,128

Coal Trade in Venice

In 1913 Venice imported 13,004,619 quintals (a quintal equals 220.46 lb.) of coal, more than twelve-thirteenths of which came from Great Britain. The sources of supply and quantities were: Great Britain, 12,040,145 quintals; Holland, 573,756 quintals; Austria, 354,386 quintals, and Germany, 35,882 quintals. This represents a year's supply under normal conditions. In 1914 the import was smaller, the total being only 10,311,070 quintals. More than nine-tenths of this, or 9,156,080 quintals, was supplied by England; Germany was the second source of supply, with 673,000 quintals; the United States, entering the market for the first time, was third, with 379,550 quintals; and Austria was fourth, with 102,440 quintals. In 1915 Great Britain was the sole source of supply and the entire import was only 2,076,330 quintals; and in 1916 the supply that entered by sea, entirely for naval use, was only 94,950 quintals. For military reasons no figures are available for 1917; importation was made entirely by the Government, which allowed certain industries to purchase a fractional quantity of the amount they needed.

Coal—How Analyzed

By FREDERICK L. SERVISS
Golden, Colo.

SYNOPSIS—*Some terms used in coal specifications are as a rule but vaguely understood. The determination of the moisture, volatile matter, fixed carbon and ash are simple operations, but the determination of the sulphur and phosphorus content is much more complicated. The thermal content of a coal may be calculated, but a much better plan is to ascertain it exactly by burning a sample in a bomb calorimeter.*

IT IS sometimes surprising to the technical man to note how few coal operators are familiar with the tests to which their product is subjected by many purchasers. They are bewildered when they read the report of such an analysis. Volatile matter, fixed carbon, sulphur and ash are vaguely understood, but an "air dry," "as received," "moisture free," or "moisture and ash free" basis of analysis means little or nothing to them.

Undoubtedly a short, simple explanation of these several tests will be of interest and value to the practical man. This article was written with that idea in view. Short, definite explanations are given wherever necessary, in order to insure a thorough understanding of the subject. No long involved chemical or technical processes are discussed, other than those required, and these are then made plain in simple language.

Coal when received in sample lots at the laboratory has been prepared in a systematic manner. The sampling of anything to be analyzed is as important as the analysis itself, and must be carefully and conscientiously carried out in order to insure correct results. In preparing a laboratory sample, a large quantity of coal is started with. This is reduced to approximately the same size and thoroughly mixed. In mixing, care must be taken to have each portion a representative of the whole. If too bulky, the sample is reduced by quartering. The ordinary laboratory-size sample is about one pound, or nearly 450 grams, the gram being the unit of weight employed in analysis.

The sample is next crushed so as to pass through a 60-mesh screen, either by rotating it in an air-tight ball mill or otherwise. After being crushed, the coal is passed through an automatic sampler which reduces the size of the sample by halving it, until a small sample of about 50 grams is obtained. From this it is easily seen why special care must be taken to insure an intimate mixture at the start. This 50-gram sample is passed through a 60-mesh sieve, any larger lumps are removed, crushed by hand, and added to the sifted portion.

Should the analysis be made upon an "as received" basis, the sample is placed in a bottle and sealed. This bottle is large enough so that the coal will not fill it more than two-thirds full. It is then agitated either mechanically or by hand until it is certain that the coal is thoroughly mixed. It is now ready for the analyst.

Assuming that the analysis is to be made on the basis of "air dry," the coal when received at the laboratory, the 60-mesh sample, is first weighed and then placed in a drying oven and dried at about 95 deg. F. for 8 hours, after which it is again weighed. The loss in weight is known as the "air drying loss," but must not be regarded as accurate, or that a high loss is indicative of poor coal. In coal analysis, the following constituents are determined: Moisture, ash, volatile matter, fixed carbon, sulphur, phosphorus, calorific or heating value, specific gravity, true and approximate.

The use to which the coal is to be put determines whether or not all or only certain of the foregoing constituents shall be determined. In the iron and steel industry there are certain elements in the coal which, if not determined accurately, will affect the resulting product. Phosphorus and sulphur are most detrimental and must be carefully checked. The ash content is determined accurately for this kind of work, in order that the calculations for the amount of limestone to flux the ash may be made. Coke is almost universally used in the iron industry, but the same analysis will apply to coke as to coal.

Efficiency of Coal Reduced by Moisture

Moisture in a coal reduces its heating efficiency. One per cent. of moisture averages a loss of 13 B.t.u. for each pound of coal burned, or at a rate of 26,000 B.t.u. per ton. From this it is evident that moisture is detrimental, even in small amounts; besides it also reduces the rate of combustion.

Ash, or earthy matter, in a fuel is of considerable importance in determining the heat value of a coal. Moisture is determined by drying one gram of the coal, "as received," in a weighed crucible. The crucible is heated to 230 deg. F. for an hour. It is then cooled in an air-tight container to prevent reabsorption of moisture from the air, and weighed when it reaches room temperature. Where great accuracy is desired, the moisture content analysis must be made upon samples of coarse as well as finely ground coal. When, as is usually the case, more moisture is found in the coarse sample, a correction must be applied to the results but the determination of this factor is of interest to the analyst alone and need not be taken up here.

The ash is determined by burning a weighed amount of coal, usually a gram, from the previously prepared air-dried sample, in a small crucible over a low gas flame, until the coal is free from carbon and all the volatile matter driven off. Slow heating is necessary in order to prevent coking and render the coal more easily burned to ash. The crucible is finally heated to bright redness until all black material is burned out.

The crucible with its contents is cooled to room temperature and weighed. It is heated to redness again for 30 min., cooled and weighed again, and so continued until the difference between two successive weights is 0.005 gram or less. The residue left in the crucible represents the ash content of the coal and is expressed in per cent.

Volatile matter is determined by placing one gram of the undried powdered coal in a weighed crucible having a closely fitting cover. This is heated over the free flame of a bunsen burner for 7 min., cooled and weighed. The loss in weight minus the moisture content of one gram represents volatile matter and is expressed in per cent. Fixed carbon is found as follows: 100 minus the sum of the ash moisture and volatile matter is known as fixed carbon and is also expressed in per cent.

The determination of sulphur is more exact, and to understand it a certain knowledge of chemistry is desirable. Sulphur in coal exists in many forms, among which are pyrite or iron sulphide, organic sulphur and compounds of sulphur known as sulphates. By heating a weighed amount of the coal in a crucible with a definite mixture of magnesium oxide and sodium carbonate, with access of air, the sulphur and its compounds are changed to alkaline salts which are dissolved by boiling in distilled water. This is now filtered to separate the solution from the solid matter.

How to Determine Sulphur Content

Bromine water and hydrochloric acid are added to the clear solution, which is again boiled; after boiling for a few minutes to expel the bromine, a solution of barium chloride is added slowly, drop by drop. Upon the addition of the barium chloride a cloudy, white precipitate is formed, which is insoluble. After allowing this precipitate of barium sulphate to settle, it is filtered and washed with hot water, then dried. When dry it is ignited and burned until white, after which it is cooled and weighed. From the weighed barium sulphate the sulphur content of the coal may be figured by multiplying it by 0.1374.

The determination of phosphorus, like that of sulphur, must be accurate and great care must be taken in the analysis. Phosphorus may be determined in several ways, but the most used is what is known as weighing the "yellow precipitate." The ash from burning ten grams of coal is fused with a mixture of sodium carbonate and sodium nitrate, dissolved in water, acidified with hydrochloric acid evaporated to dryness, and hydrochloric acid and water again added. The insoluble matter is filtered off and the clear solution treated as follows: Nitric acid is added and the solution boiled down rapidly to a small volume, ammonium hydroxide is added until a permanent precipitate forms, then nitric acid is added until the precipitate dissolves, and a few drops are added in excess. The solution should be heated to near boiling, then a measured amount of a previously prepared molybdic acid solution is added, and the whole shaken for 15 min. The yellow precipitate which results is known as ammonium-phospho-molybdate. This is then carefully dried at 220 deg. F. and weighed. The phosphorus may be determined by multiplying the weight of this precipitate by the proper factor.

The heating power of a coal is understood to mean the total amount of heat liberated by the complete combustion of a unit weight of the fuel. It is customary to select the pound as the unit of weight, which with the Fahrenheit scale of temperature results in the British thermal unit, or B.t.u. The heating power of a coal or coke may be calculated with fair accuracy for many purposes from Dulong's or other formulas. The results thus obtained, however, are only approximate, and for accurate results the direct combustion of the fuel in a bomb calorimeter is used. The manipulation is as follows. There are many styles of calorimeters, but the principle is the same, and the method here explained will apply to almost any type.

A weighed sample of the 60-mesh coal is placed in a platinum tray. One terminal of the igniting circuit is connected to this dish, which is placed in the bomb, or heavy steel tube fitted with a tightly screwed-on cap. The cap is put securely in place. To insure ignition of the coal in the bomb a piece of fine iron wire is connected to the other terminal of the firing circuit, and placed so as to touch the coal sample in the tray.

After screwing on the cap, oxygen is pumped into the bomb until a pressure of 20 atmospheres, or about 280 lb. per square inch, is reached. The needle valve through which the gas was pumped is closed so as to allow no escape of gas. The bomb is now placed in a polished copper pail, containing a weighed amount of water, enough to cover the bomb about an inch above the top, and this pail is placed in an insulating jacket. The firing terminals are connected to the switch and the temperature of the water read accurately, often to 0.001 deg. C. The switch is then thrown, combustion takes place within the bomb, and the resulting rise in temperature of the water is noted. From the temperatures read, knowing the weight of water used and the specific heat of the bomb and the copper pail, the heat value of the coal may be determined and expressed in B.t.u.

Easy to Determine Specific Gravity

Frequently specific gravity, both true and apparent, is asked for and may be found with ease. Select a lump of the coal (one weighing about half a pound will do nicely) and weigh it. Call this weight A. Place the lump in a glass of distilled water for a few minutes, remove it and carefully wipe off the excess water, and weigh again. Call this weight B; then the increase in weight B-A, we will call C. Weigh the lump while suspended in a glass of water. Call this weight D. Then,

$$\frac{A}{(A-D)} = \textit{true specific gravity}$$

while

$$\frac{A}{A-(D-C)} = \textit{apparent specific gravity.}$$

The heating value of the coal as determined by the combustion of a sample in an atmosphere of oxygen does not give the real commercial power, since this is dependent upon the character of the furnace and its operation, as well as on the composition of the coal. Where a number of grades of different fuels are available (for say steaming purposes), it is found best to conduct a series of tests upon these fuels and determine which will evaporate the most water under operating conditions for the least money; and that which is found to be the cheapest is nearly always chosen. However, it is advantageous for a plant operator to know the heat content of the coal he uses. The evaporation of so many pounds of water by so much coal is not indicative of efficiency, therefore a determination of the heat units contained in the coal is essential to a thorough knowledge of its value.

Some Characteristics of American Coals in Byproduct Coking Practice—III

By F. W. SPERR, JR.
Chief Chemist, The Koppers Co., Pittsburgh, Penn.

SYNOPSIS—*There was a time when the analysis of a coal gave little indication as to its coking qualities; its physical appearance was supposed by be a safer guide in this connection. This was true of beehive oven practice. With the extension of the byproduct coke oven and a more intimate acquaintance with the various coals new theories have been adopted.*

THE geological age of a coal is no criterion as to its coking quality. As good byproduct yields and as good coke are obtained from the comparatively recent coals of Colorado as from the early carboniferous strata of Pennsylvania. The coking properties of the Lower Kittanning seam undergo most remarkable changes parallel with the extent of devolatilization southeastward from Allegheny and Fayette Counties, Pennsylvania, to the Potomac basin in Maryland. The phenomena of prime importance seem to be those of deoxidation rather than of devolatilization. The highly oxygenated coals of Illinois may have less volatile matter than coal from a portion of the Pittsburgh seam and yet produce a much inferior coke. In fact, the best basis we have for differentiation, with respect to coking quality, seems to have close relation to high- or low-oxygen content. We might make the above com-

Examples	Low-Oxygen Coking Coals: Appalachian Bituminous Coal Fields	High-Oxygen Coking Coals: Illinois, Indiana, Washington
Shape	Blocky	Slender, tapered, fingery
Hardness	Hard	Soft
Exterior surfaces	Even	Sometimes smooth; but often having transverse seams or sometimes even masses of pebbly carbon
Cell-structure	Regular—usually rather heavy cell walls	Irregular—thin cell walls
Byproducts: Gas	High yield—rich—little CO or CO_2	Low yield—lean—much CO and CO_2
Tar	High yield—thicker—high specific gravity—less tar acids	Low yield—thin—lower specific gravity—more tar acids
Ammonia	Normal	Often higher
Benzol	Normal	Irregular
Combined water	Low	High
Rate of coking	Normal	Slow
	The excess of fusible bituminous matter accumulates in the upper center of the oven, forming a wedge-shaped, honeycombed mass, called "sponge"	Any excess of fusible bituminous material forms pebbly masses more or less loosely agglomerated and not always confined to the center of the oven

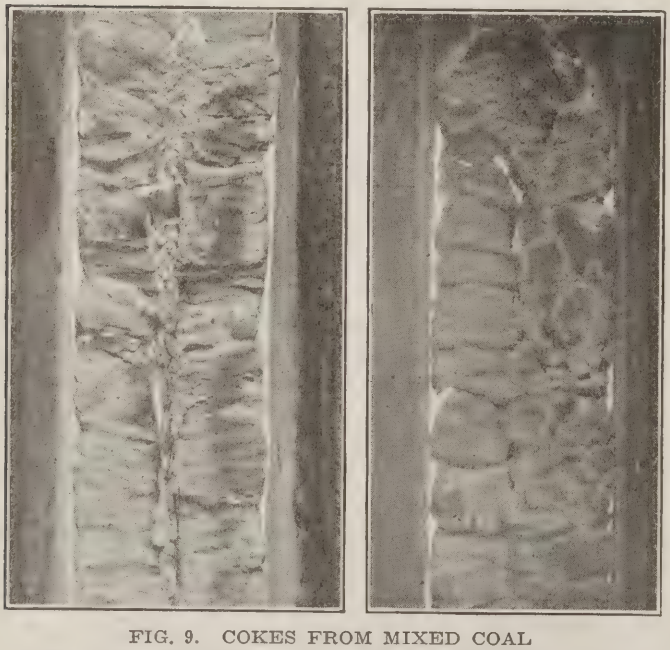

FIG. 9. COKES FROM MIXED COAL

Left—Coke from mixture of 85 per cent. Pittsburgh + 15 per cent. Pocahontas coals; made slowly in wide oven; thirty hours' coking time; appearance in oven. Right—Coke from mixed coal: 85 per cent. Pittsburgh + 15 per cent. Pocahontas; made rapidly in wide oven; sixteen hours' cooking time; appearance in oven; note sponge in upper part.

TABLE V. SULPHUR ELIMINATION IN COKING COALS IN KOPPERS OVENS

State	County	Seam	Coking Time, Hours	Coke Yield, Per Cent.	Sulphur: Per Cent. in Coal	Sulphur: Per Cent. in Coke	Sulphur: Per Cent. of Total Eliminated	Sulphur: Per Cent. of Total Retained

FIG. 10. COKE FROM MIXTURE OF 85 PER CENT. PITTSBURGH + 15 PER CENT. POCAHONTAS COALS
Made slowly in wide oven; thirty hours' coking time; appearance on bench

parisons of these two kinds of coal with approximately the same percentage of volatile matter.

It would be very interesting to compare the results of normal geological deoxidation, such as has occurred in parallel undisturbed strata, like the Freeport, Kittanning and Pittsburgh seams in Allegheny County, Pennsylvania, with what one might term "accelerated deoxidation," such as has occurred from the western to the eastern portions of the Lower Kittanning seam. Additional data must, however, be accumulated before we can begin to generalize on this subject. The famous Pittsburgh seam is the most regular and dependable of any with which we have to deal. Even in this seam, however, the percentage of volatile matter drops gradually from about 37 per cent. in the western portion to about 27 per cent. in portions of the Connellsville basin. Attention has heretofore been given principally to this phenomenon of devolatilization, and it would be interesting to study the variation in coking quality from the standpoint of deoxidation. Here the differences in oxygen content are relatively smaller, and, in spite of the considerable range of volatile matter, we actually find comparatively small differences in the coking quality of different parts of the seam.

Fig. 9 shows coke made from Pittsburgh coal + 15 per cent. Pocahontas in ovens of 20 in. average width, coked 17 hours and 30 hours respectively, heats having been adjusted to the coking time. Figs. 10 and 11 show the cokes from these ovens on the bench. Please note the difference in the amount of sponge, which is quite characteristic. The 17-hour coke, although it is smaller sized and more cross fractured, is stated to give excellent results in the blast furnace. In ovens somewhat narrower, such as those at St. Paul, and with a coking time of 19 hours, the Pittsburgh coal gives very little sponge.

The Elkhorn coal, the development of which in the last few years has been one of the prominent events in the coal industry, appears to occupy a position midway between the eastern high-volatile coals and the more highly oxygenated coals of Illinois and Indiana. Its low ash and sulphur content and high byproduct yields place it in the first rank of our best coking coals. It makes no sponge; but the coke shows some pebbly carbon like that characteristic of Illinois coals.

The data (Table V) showing the elimination of sulphur in coking various coals in byproduct ovens are of considerable practical importance. The figures for Alabama coals and for mixtures of Pennsylvania with West Virginia, and Pennsylvania with Kentucky coals

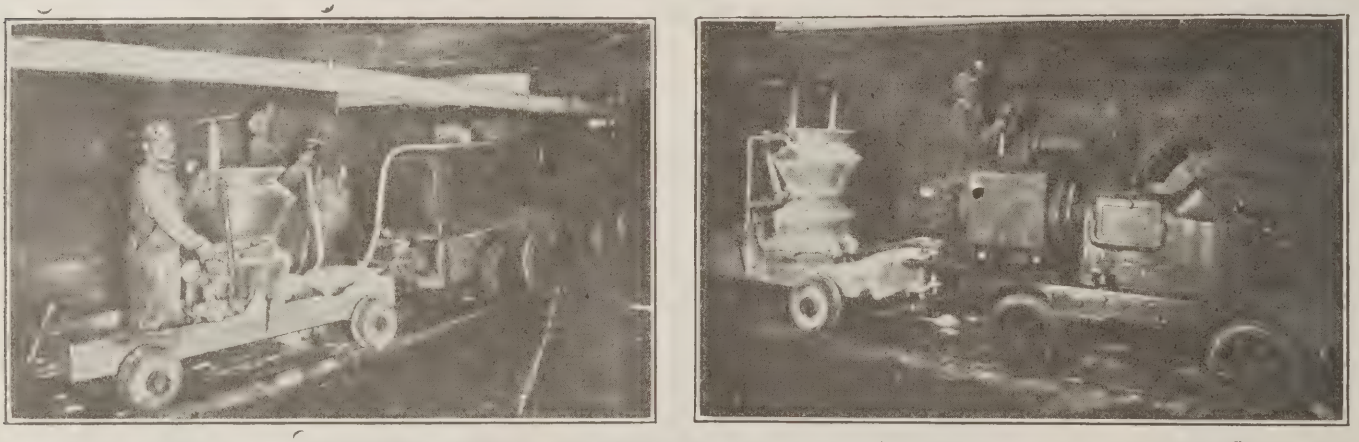

FIG. 11. COKE FROM MIXED COAL; 85 PER CENT. PITTSBURGH + 15 PER CENT. POCAHONTAS
Made rapidly in wide oven; sixteen hours' coking time; appearance on bench

are each averaged from a large number of tests; the other figures are from individual tests. Please note the high percentage expelled in coking Pittsburgh coal and the lower percentage from the higher oxygen coals of Washington and Kentucky. J. R. Campbell[1] has observed the higher percentage of sulphur elimination in the byproduct oven, and states that in beehive practice they figure on about 20 per cent. elimination.

Use of the Cement Gun in a Bituminous Coal Mine

By M. S. Sloman
Pittsburgh, Penn.

Numerous experiments have been made and exhaustive tests conducted by the Bureau of Mines and various coal companies in the bituminous fields on the application of a cement coating on roofs and ribs to prevent weathering and the costly falls of rock arising from this cause. While considerable work has been done in this direction, the results obtained have, until recently, been considered of rather questionable value by some who have been waiting to see the condition of the coating after it had been applied for a considerable length of time. The United Coal Corporation, of Pittsburgh, Penn., with several large operations, was one of the first to become interested in this subject, and the results obtained by it seem to prove conclusively that a cement coating, properly applied, will form a permanent barrier to the action of weathering on roofs susceptible to air slacking.

TWO VIEWS OF THE CEMENT GUN AT WORK IN THE EDNA MINE

The work has been carried on at the Edna No. 1 mine, located at Adamsburg, Westmoreland County, Penn., near Pittsburgh, where it is working the Pittsburgh seam, averaging 6 ft. in thickness, with the characteristic roof coal of about 12 in. and above that a slate and clay composition containing limestone which is readily disintegrated by contact with air. Without question this cement-gun coating was applied under adverse conditions. The coal is taken from the mine through a main slope, first started some 18 years ago, and driven in 6500 ft. Trouble has been encountered from the start due to falls of roof, as evidenced by the average distance from the coal to the roof, which is about 12 ft.—frequently the road was completely blocked by such falls, necessitating the closing of the mine on an average of three or four days every summer. Owing to the risk involved, no man-trip could be run and the miners were obliged to walk in and out from work. It was on this slope that the work was started on Nov. 1, 1917.

The equipment consisted of a "N-1" cement gun. Essentially this consists of a hopper with control valves for mixing the material and a nozzle at the end of a hose, where the dry sand and cement, conducted under air pressure, are mixed with water and directed at high velocity onto the surface to be coated. This apparatus is mounted on wheels of suitable track gage, making it entirely portable.

In this mine, as in many others electrically equipped, there is no supply of compressed air available. To meet demands of this nature, a Sullivan electrically operated portable air compressor was developed. This can be conveniently taken into the mine to the location of the work.

Since there was no supply of water under pressure available for this use at the Edna mine, an ingenious system was used. A large tank, of a size to hold sufficient water for a shift, was mounted on a mine car; a connection was made with the air receiver and this water, brought under pressure, was forced up to the spraying nozzle.

The work is done at night by a crew consisting of from 5 to 8 men. One man operates the gun, one the compressor (also serves as general mechanic), two others mix the material and one operates the nozzle; in addition, the following men are employed outside for part of their time: One hauls material, one dries sand and one handles the hoisting rope when the machine is working on the grades.

It was found that the mixing could best be done outside the hopper, and accordingly wooden boxes are used for that purpose and the mix dumped into the hopper. The mix consists of three parts fine sand (and this must be thoroughly dry) to one part Portland cement. The air pressure for the most effective work should be from 40 to 60 lb., while the water should be under a pressure about 20 lb. higher if possible.

The surface to be coated is first thoroughly cleaned and scaled. This is most essential. It is the opinion of Mr. Maize, the local superintendent, that where possible the use of a stream of water would prove very effective. No wire or reinforcement of any kind is used in coating the bare roof and side walls, and the coating is applied direct, averaging ½ in. in thickness.

[1]Trans. American Institute Mining Engineers, 1916, liv, p. 181.

Pieces of coating afterward broken off show a perfect bond existing between the cement and the substance composing the surface, whether it be coal or rock. In coating the timbers, ½ in. wire mesh is first stretched and secured to the surface before the cement is applied.

An accurate record of progress and costs has been kept from the start and these figures will no doubt prove interesting. The total cost of coating 6250 ft. of slope, averaging 12 ft. in width and 12 ft. in height on sides, has been $7488.58. This figures a net cost of 30c. per square yard.

The following figures taken at random show detailed costs on a length of 900 ft. of slope which was completed in 13½ shifts of 8 hours each.

1 mechanic	$71.85
1 engineer for rope hoist	65.48
1 operator cement gun	71.85
2 mixers at $63.45	126.90
1 man at nozzle	63.45
1 man drying sand	61.40
1 man haul material part time	23.50
540 sacks cement at 60c	324.00
1620 sacks sand at 12c	194.40
Total	$1002.83

This section figured about 36 sq.ft. per foot of advance, making the actual cost on this work 27c. per square yard of surface coated. This cost, as will be noted, included the outside engineer, which charge would not be necessary in most cases. It is interesting to note the progress made, which approximated 90 sq.yd. per shift of 8 hours.

In addition to the main slope, the entries and breakthroughs are coated. The "gun" has also been used with success in making stoppings air-tight and in building up permanent stoppings.

This can be done by building up a wall of loose rock and then applying a thick coating of cement. An excellent air-tight stopping is the result.

It would seem that the coating has stood a sufficient length of time on the slope to enable one to judge as to its permanence. A large part of the coating has withstood the rigors of the coldest winter yet experienced, and the heat of an extremely hot summer. It is today in excellent condition and looks as strong and unbroken as when first applied. In a few exceptional cases only, and these confined to small areas, has any spalling of the coating occurred. This was attributed entirely to improper cleaning of the wall before the coating was applied. The beneficial results obtained at this mine have been such as to more than offset already the initial cost of the equipment and the cost of the work. Not a single fall of roof has taken place in sections coated and, consequently, there has been no forced closing of the mine as was previously the case. This saving alone can be computed in dollars and cents. A regular man-trip is now run in and out of the mine and the elimination of the long walk on the part of the miners has done much to make them more contented and efficient during times of maximum production.—*Mine and Quarry.*

Coal Roof Support

An operator possessing a thick seam of coal at times has some of the advantages and disadvantages of a person with a fat wallet. He is fortunate in having surplus coal to spare if demanded, but when used for purposes where recovery later is doubtful, it might be an advantage if the seam was not of sufficient height to permit of its being so used. This thought was suggested by the accompanying illustration, which shows an entry in the Pittsburgh seam in the northern part of West Virginia.

At the mine where this photograph was taken this coal seam runs about 7 to 8 ft. in thickness. Immediately above the main portion of the bed there is often a bad drawslate, on top of which generally is a bench of inferior coal. It has been found safer and more economical under such circumstances to leave up from 4 to 8 in. of coal to serve as a top. The unfortunate part of this plan is that this top coal is generally lost. From a conservation standpoint it is a waste.

An experiment has been tried in recent years to supplement the coal roof noted by arches of coal in entries. Over a mile of straight entry was thus driven and a good opportunity given to note the results of this method of roof treatment. In the illustration a curved arch is shown starting just beyond the patent mine door, which is standing open temporarily. Another form of arch was also tried in which the lines of the arch are straight, the corners at the top being diagonal, along the lines a brace would take if used in timbering. This latter form was called a "box" arch. In shooting the coal at the entry face three shots were placed—a center shot and one on either side—all near the top. The arch was then trimmed up by pick to the shape desired. The arch is not favored by the company operating the mine where the photograph was taken, one reason being given

CURVED-ARCH COAL TOP AND PATENT DOOR

that when electric wires are strung along the top the arch coal must be taken down. It is most desirable to avoid the use of timber props on haulageways, and a number of substitutes have been tried to hold up the roof, among such being a coal arch. The entry illustrated is from 10 to 11 ft. wide and the arch support was an interesting experiment.

It was fortunate that a photograph of the entry showing the coal roof support includes a view of a Canton automatic mine door, made by the American Mine Door Co., of Canton, Ohio. The details of this equipment are more clearly indicated on account of the door being open. The operation and advantages of this device are so well known to coal men as to need little comment. By its use the human element is done away with, and with its elimination the great danger to the trapper attending the oldtime door. It has been appropriately stated that even a runaway car or trip passes through this automatic door as safely as a slow mule. The door is the result of years of experimentation.

The Fuel Problem of Brazil

Prepared for *Commerce Reports* by the Latin American Division, Bureau of Foreign and Domestic Commerce

SYNOPSIS — *Rich in vast tracts of land suitable for agricultural and grazing purposes, Brazil is handicapped by the lack of fuel. During the war the country was forced to depend mainly on her own resources for fuel. An analysis of Brazilian coals shows that when used with the steam engine they deliver more horsepower per pound of coal than do the best grades of Pocahontas or New River. Federal Government aids development by making loans.*

THE war has served to accentuate sharply the absence of adequate supplies of native fuel in Brazil. The restriction of imports, first from Europe and now from the United States as well, has forced the Republic for the first time in its history to depend upon its own resources. Recent Latin American circulars issued by the Bureau of Foreign and Domestic Commerce on the Brazilian trade balance and foreign exchange and on the war and Brazilian foodstuffs summarize briefly the rapid strides which Brazil is making toward economic independence and the diversification of her agricultural products. Rich in vast tracts of fertile land suitable for agricultural and grazing purposes, possessing roughly some 1,500,000 square miles of timberland, and the fortunate owner of extensive deposits of iron and manganese, Brazil is finding itself hampered at every turn by the shortage of one prime necessity—fuel.

A coal commission, appointed by the Federal Government, made an extensive examination of the coal fields of the country during 1904 and 1905 and reported the existence of coal suitable for briquetting in the three southernmost states—Rio Grande do Sul, Santa Catherina and Parana. Thin coal seams of inferior quality were also reported in Sao Paulo and lignitic coal has been discovered along the tributaries of the Amazon in the States of Para and Amazonas. The oil resources of the Republic are apparently confined to the oil of the Bahia region, and a rather indeterminate area of scattered indications in the interior. Wood is the native fuel which is abundant in all parts of the country. No list of Brazilian fuel resources is complete, however, without a mention of the hydroelectric possibilities of the many powerful waterfalls and cascades which are fortunately prevalent in the accessible coastal highlands and along the edges of the interior plateau. In fact, the recent industrial development of Rio de Janeiro and Sao Paulo is largely due to the availability of ample water power.

Before the war it was easier and cheaper to import coal than to attempt the mining of the native product, which was inaccessible and of inferior quality. Fuel oil was apparently in little demand before 1913. Wood was used where coal could not be obtained, but proved an expensive and wasteful fuel. Comparatively little capital was used for the equipment necessary to generate and utilize hydroelectric power. Hence, prior to 1914, with the exception of wood, the greater part of the fuel used in Brazil was imported.

The restrictions placed upon exports of fuel by the allies since the beginning of the war and the accompanying high prices have forced Brazil, temporarily at least, to resort in part to native fuel. Under this stimulus Brazil is beginning to exploit her native coal fields and is experimenting with oil extracted from the Bahia shale. For the most part, however, the present shortage is being relieved by the increased use of wood. Although the import figures for the war years 1914-1917 can not be said to equal the consumption as the import figures for prewar years do, it is nevertheless true that only a small per cent. of the shortage occasioned by the decreased imports has been met by native fuel.

The accompanying tables show the steady increase in the quantities of fuel imported during the four-year period immediately preceding the war and the steady decrease during the four-year period of the war, coupled with the increase in cost.

The following table, compiled from official Brazilian statistics, contrasts the steady increase in the quantities of fuel imported during the four-year period immediately preceding the war with the steady decrease during the four-year period of the war. Bitumen, the last article listed in the tables, includes coal tar and oil for manufacture of gas:

Fuel	Prewar Imports				War Imports			
	1910 Metric Tons	1911 Metric Tons	1912 Metric Tons	1913 Metric Tons	1914 Metric Tons	1915 Metric Tons	1916 Metric Tons	1917 Metric Tons
Coal	1,581,718	1,736,213	2,098,842	2,262,347	1,540,126	1,163,760	1,024,486	818,327
Briquets	181,620	220,136	206,804	230,049	241,977	108,706	64,351	5,908
Coke	9,954	12,584	12,563	17,164	9,128	3,820	2,484	1,703
Mineral fuel oil	.....	.....	.....	9,680	35,058	61,465	100,623	51,154
Bitumen	848	698	1,599	1,907	454	448	441	583
Total	1,774,140	1,969,631	2,319,808	2,530,156	826,743	1,338,199	1,192,385	877,675

The war period has been characterized by two important factors in the increase in price of imported fuel and the shifting of the chief source of supply from England to the United States.

An analysis of the 1913 imports shows that England supplied over 1,900,000 metric tons of coal, 237,000 tons of patent fuel, 14,000 tons of coke, and 900 tons of bitumen, or about 86 per cent. of the total fuel imports for the year, while the United States only supplied 274,789 tons of coal, 2200 tons of fuel oil, and 100 tons of bitumen, or about 11 per cent. of the total fuel imports for the year.

In 1917 the United States supplied 642,428 tons of coal, the principal item of import, or 78.5 per cent. of the total amount imported during the year, while England only supplied 172,866 tons, or 21 per cent. of the

total imports. The imports of all forms of fuel have been decreasing since the war, with the one exception of fuel oil, which has been increasing. No statistics are available showing the origin of imports of oil for 1917, but during 1916 the total imports amounted to $1,375,154, of which $1,024,627 came from Mexico and $169,446 from the United States.

According to the Retrospecto Commercial, a ton of best quality Cardiff coal, which sold for 48 milreis before the war, was worth 110 milreis in 1916, an increase of 129.16 per cent. This increase must, of course, be attributed in part to the decline in the value of the Brazilian paper currency as well as to the increased cost of coal itself and increased cost of transportation. The following table shows the enormous increase in the cost of imported fuel during the period 1913-1917. The prices are quoted in paper milreis, per metric ton, c. i. f. Brazil:

Fuel	1913, Milreis	1914, Milreis	1916, Milreis	1917, Milreis
Coal	27	27	76	114
Briquets	34	31	77	93
Coke	37	34	133	194
Mineral fuel oil	66	43	57	91
Bitumen	115	140	272	299

Only a small per cent. of the enormous deficit of 1,600,000 tons shown in the 1917 imports as compared with the 1913 imports has been supplied by the increased production of native fuel. Obviously, there is no possible means of determining this per cent., but the following paragraphs at least give some idea of the fuel now being produced in Brazil.

Government Encourages Use of Native Coal

The Federal Government is anxious to encourage the production of native coal and has agreed to give it preference whenever possible, considering its prices and quality. Aid is to be given in the construction of railroads for transportation purposes and Government-owned ships are to carry native coal, coke, pitch and the pyrites and residue from which sulphur may be made at the lowest possible rates. A Federal decree of Mar. 30, 1918, authorizes the making of loans to coal-mining companies under certain imposed conditions.

A detailed analysis of tests made in the United States and Germany from samples of Brazilian coal is included in an article entitled "Coals of Brazil," by I. C. White, published in *Proceedings* of the Second Pan American Scientific Congress, Volume VIII (Washington, 1917). The Santa Catherina and Rio Grande do Sul coal averages about 35 per cent. ash, of which approximately 6 per cent. is sulphur in the form of nuggets of iron pyrites. By crushing and washing operations this ash may be reduced to about 14 per cent. and the sulphur to six-tenths of 1 per cent. in perhaps 33 per cent. of this coal, which may then be successfully briquetted. In an additional 42 per cent. the ash may be reduced to about 25 per cent. and the excess sulphur eliminated, thus yielding a fair grade of slack. From the remaining 25 per cent. of waste material the iron pyrites may be utilized for the manufacture of sulphuric acid as a byproduct.

The following table, included in Mr. White's article, "Coals of Brazil," gives the results of the analyses of 21 samples of Brazilian coal collected by the commission in the field. The samples selected include varieties of coal found in the fields of Rio Grande do Sul, Santa Catherina and Parana:

Sample No.	Moisture	Volatile Matter	Fixed Carbon	Ash	Sulphur	Phosphorus	B.t.u.
1	1.64	14.25	38.17	54.94	3.05	0.019	8,731

Analyses of briquets made from the purified Brazilian coal show that while their fuel value is slightly inferior to that of the best grade (Crown) Cardiff briquets, it is equal or even superior to that of the Anchor brand, which is extensively used in Brazil.

The coal fields now being exploited are located in the Jacuhy River Valley, in Rio Grande do Sul, and in the Tubarao district in Santa Catherina. The most important mine in Brazil is located at Sao Jeronymo, about 20 kilometers south of the Jacuhy River, near Porto Alegre. This mine is reported to be owned by Dr. Luis Beten Paes Leme, a Brazilian engineer, and is operated by the Sao Jeronymo Mines and Railway Co. The output is carried down to the river by the company's privately owned railroad and is marketed from Porto Alegre, at the mouth of the river, from Pelotas and from Rio Grande do Sul. Two shafts are now being worked, with a total average daily production of about 650 tons, and a third shaft is being sunk, which will probably increase the daily production to between 1000 and 1200 tons. Over 40,000 tons were shipped to Rio de Janeiro during the three months ending July 15, 1918. The product from this mine is a deep-mined coal, high in volatile matter, and supplies Pelotas with good gas and salable coke.

In March of the present year Sao Jeronymo coal was selling for 60 milreis (about $15) per ton at Pelotas and at the port of Rio Grande do Sul. A government loan amounting to $325,000 American currency was recently made to this company, the security being a mortgage on the property of the company.

An analysis of some 20-odd tons of the Sao Jeronymo coal was made by the United States Geological Survey, with the following results: Moisture, 11.52 per cent.; volatile combustible, 26.75; fixed carbon, 40; ash, 21.93. Tests were made in the manufacture of producer gas for the gas engine and these were said to show that the fuel would develop more horsepower per pound of coal than could be obtained by the best grades of Pocahontas or New River fuel when used in connection with the steam engine.

Near the head of the Jacuhy River, in the northern part of Rio Grande do Sul, a large mine is being worked by the Jacuhy Co. This mine is understood to be partially owned by the government, which is aiding in its development with loans and is building 60 kilometers of railway line to connect it with the River Jacuhy. A consular report states that this mine had reached a depth of 60 meters in January of the present year. By

July the production was expected to be between 6000 and 12,000 tons per month, and these amounts were to be increased by the end of the year.

In addition to these two large mines now being worked in Rio Grande do Sul operations are being initiated in the Jaguarao River Valley, in the southern part of the state, near Rio Negro, Candiota and Santa Rosa. This coal is of the surface variety and is poorer quality than the Sao Jeronymo product. It sells for about 15 to 20 milreis (about $3.75 to $5) per ton at the place of extraction. Abundant evidence of favorable outcroppings in the Jacuhy Valley indicates deposits besides those now being developed.

The chief coal deposits of the State of Santa Catherina are located in four river valleys situated near the coast in the southern corner of the state. A short line, part of the Sao Paulo-Rio Grande system, runs inland from the port of Imbituba and Laguna to Minas, or Lauro Muller Station, as it is now called, and the Government has contracted with the company for the construction of two additional branches to serve the coal mines of this region. One of these branches is to extend from the Tubarao River south 80 kilometers to Arangua and the second from a convenient point on the Paranapanema branch through Barra Bonita to the coal mines at Rio do Peixe.

The firm of Lage Irmaos, which operated in the Tubarao district, is reported to be producing from 60 to 70 tons daily and is desirous of developing its properties further. At present the company is hampered by lack of rails for railroad construction and is transporting its output by oxen. With sufficient railway facilities, it is reported the output could be increased to between 300 and 400 tons per day. The Barra Bonita Mining Co. was organized June 12, 1918, under the laws of Brazil, with a capital of 2,800 contos of reis (about $700,000), represented by 14,000 shares of 200 milreis each (about $50), all of which has been fully paid up. The majority of the stock is owned by the Federal Real Estate and Mortgage Company.

The Companhia Industrial de Gamdarella, a corporation with headquarters at Rio de Janeiro, has just been incorporated for the purpose of exploiting deposits of coal, iron, manganese, and other minerals in the "Gandarella" property in the municipality of Santa Barbara, State of Minas Geraes. The company is incorporated for 3000 contos ($750,000), which may be increased to 5000 contos ($1,250,000). Of the initial capital stock 2500 contos ($625,000) is represented by property and 500 contos ($125,000) by cash subscribed. The stockholders are all Brazilians. The Carbonifera Riograndense Companhia has received Government loans amounting to $375,000. No definite information concerning this company's operations is available.

To enter a mine after a disaster the compartment of the shaft that can be quickest used for descent should be chosen, but the choice of a compartment will be governed by the facilities at hand for lowering and hoisting. If an auxiliary hoisting engine is in place, much time may be saved by employing it. A crown pulley or sheave wheel may have to be placed above the shaft. The pulley should have a diameter at least 30 times that of the rope or cable used.

Legal Department

INJURY TO TIMBERMAN — Plaintiff, a miner of 15 or 16 years' experience, was employed as an independent contractor to drive an air course in defendant's mine. Two weeks later he was injured through a fall of roof while working as an ordinary employee in the same place, under general orders to timber. At the particular place he had sounded the rock just before the accident, and regarded it as safe. On these facts, the Alabama Court of Appeals holds in the case of Thrasher vs. Red Eagle Coal Co., 78 Southern Reporter, 718, that defendant operator was not liable in damages on account of the accident, on the theory of negligence in failing to discover and guard against the defective condition of the roof before ordering plaintiff to work at that point.

TERMINATION OF MINING LEASES — Plaintiff sued to recover $1000, as a minimum annual royalty under an Iowa coal-mining lease. Defendant denied liability on the ground that plaintiff's right to royalty had ceased under the terms of the contract, which was to run for twenty years, unless the coal should be sooner removed; asserting that all minable coal had been removed and the royalty thereon paid prior to the term for which the plaintiff sued. Deciding the case in favor of plaintiff lessor, the Iowa Supreme Court holds that the defense failed because defendant failed to prove a surrender of the lease with appropriate notice to the lessor of intention to surrender on the ground that all the minable coal had been removed—a controverted fact. The court said: "As long as the lessee held any right under such lease it operated as a continuing incumbrance upon the property of the lessor. It also saved to the lessee the speculative chances of the future and deprived the lessor thereof accordingly. It would seem therefore elementary justice that as long as the lessee claimed any of the benefit of the lease it should be subject to the burden. On its face the lease was valid and binding upon both parties until one or the other should elect to terminate it according to its terms. If the lessee desired absolution from further payment of the minimum royalty it fairly devolved upon it to take an irrevocable position to that end and to so notify the lessor. An acceptance by the lessor would indisputably terminate the lease. A refusal by the lessor would make an issue which could be litigated if necessary." (Fisher vs. Maple Block Coal Co., 168 Northwestern Reporter, 110.)

ALABAMA VENTILATION LAW INTERPRETED—In an action for death of a miner due to an explosion of gas in an Alabama mine—Segrest vs. Roden Coal Co., 78 Southern Reporter, 756—the Alabama Supreme Court lately applied the statute of that state, enacted in 1911 and providing that the minimum amount of air to be supplied to a mine shall be 100 cu.ft. per minute per man and 500 cu.ft. per mule or horse. Holding that this statute is designed to protect miners against dangers incident to both noxious and explosive gas, and requires gas to be so diluted as to render it harmless, the court said: "We still think that it was the intent of the Legislature to protect the miner from the danger of noxious and explosive gases generated in the mine, and that this is a non-delegable duty. . . . Had the Legislature provided merely the supplying of a certain amount of air, instead of requiring that the gas be diluted, carried off, and rendered harmless, the mine owner would, no doubt, meet the statutory requirement by supplying the requisite amount. But this was not done, and the amount of air provided is a legislative ascertainment that nothing short of the amount of air so prescribed will accomplish the purpose. The result is the law requires the mine owner, or superintendent, to see that all noxious and explosive gases generated in the mine are so diluted or carried out as to render the same harmless, and that nothing less than air to the extent of 100 cu.ft. per man per minute and 500 cu.ft. for mule or horse will accomplish the purpose."

Boiler-Scale Prevention

Illinois recently had a "Scale Prevention Week." In every plant scale prevention may be studied with profit. The following open letter from the Fuel Conservation Engineer of the United States Fuel Administration presents the subject well

THE importance of this subject can be appreciated better when it is realized that no boiler is without scale and that all scale results in fuel loss. Exceptions to this rule are so few as to be negligible.

The very fact that it is necessary to use a tube cleaner or turbine is sufficient evidence to prove that there is scale in your boiler. It makes no difference whether the boilers are turbined once a week or once a year, the average thickness of scale is equal to one-half the thickness at the time of removal. Another thing that must not be overlooked is that the only proper place to remove the scale-forming elements is before the water enters the boiler. This is easily done and is the economical thing to do.

Careful and extensive experimentation in this matter has been conducted by Professor Schmidt, at the University of Illinois. Table I is based on the results of his researches.

TABLE I. LOSS OF EFFICIENCY FROM SCALE

Character of Scale	Thickness, In.	Composition	Loss of Eff., Per Cent.
Hard	1/50	Mostly carbonate	5.4
Soft	1/32	Mostly carbonate	7.2
Hard	1/32	Mostly carbonate	8.5
Soft	1/25	Mostly carbonate	8.0
Hard	1/25	Mostly sulphate	9.3
Hard	1/20	Mostly sulphate	11.1
Soft	1/16	Mostly sulphate	10.8
Soft	1/16	Mostly carbonate	11.0
Soft	1/16	Mostly carbonate	12.4
Hard	1/16	Mostly carbonate	12.6
Soft	1/11	Mostly carbonate	15.0
Hard	1/9	Mostly sulphate	15.9

Do not be content with the thought that you are having no trouble with the scale. You will have no trouble only when you have no scale. Why wait until you have bagged the boiler, burned out the tubes or wasted a lot of coal before taking action in this matter? Impress upon your memory the fact that the first thin layer of scale is the most injurious. Stated somewhat more scientifically, the rule is that the insulating effect of scale varies as the square root of its thickness. Thus, the insulating effect of scale of thicknesses proportional to 4, 9 and 16 is in the ratio between 2, 3 and 4. To give this matter point and talk in terms of coal, Table II is given.

TABLE II. COAL WASTED BY SCALE

Average Thickness of Scale, In.	Coal Wasted from Every Ton Fired, Lb.
1/50	100
1/32	140
1/25	180
1/20	200
1/16	220
1/11	300
1/9	320

The use of boiler compounds is unquestionably better than no treatment at all, but it seldom, if ever, accomplishes really satisfactory results. If the compound is a chemical and reacts with the scale-forming material in the water, it can only change this material to something else, which is commonly known as "sludge." When this forms it is deposited on heating surfaces of the boiler as a soft mud-like substance which is not scale, but which has an insulating effect and which, if excessive, may actually result in the plates of the boiler being burned. To avoid the sludge accumulating in excessive quantity the boiler is blown down frequently, which causes a direct loss of heat and waste of coal.

It will be observed from the foregoing that no middle ground is taken in this matter. There is only one right condition and that is perfect cleanliness. If it is thought that there is an objection to properly softening the feed water before pumping it into the boilers, due to the cost of the installation necessary, look over Table II and figure out what it costs now per year with the present water and its consequent scale. In all probability it will be found that the cost of proper water treatment would be paid for within two years, including the cost of operation. Water as pure as that in Lake Michigan comes in this class.

In conclusion, remember that it is possible to so purify the water that no scale will form in the boilers.

British Mine Accidents and Their Causes

SPECIAL CORRESPONDENCE

SYNOPSIS — *This article is an analysis and commentary on the report of the mine inspectors of the United Kingdom. In Britain, as elsewhere, the majority of fatalities arise from falls of roof and top rock; some result from falling coal, some from explosives, explosions and other causes. Downright carelessness is the source of not a few fatalities.*

AT THE mines in the United Kingdom 1,023,400 persons were employed in the year 1917. The coal raised amounted to 248,473,119 long tons and there were 1370 deaths from accident. In round numbers this represents a production of 243⅓ tons per person employed, a death rate of 1.34 per thousand persons, or 5.5 per million tons of coal mined.

Of the deaths 174 occurred in Scotland, 218 in the Northern Division, 335 in the York and North Midland Division, 153 in the Lancashire, North Wales and Ireland Division, 366 in South Wales and 124 in the Midland and Southern Division. Arranged according to cause, 20 deaths were due to explosions of firedamp or coal dust; 724 to falls of ground; 62 to shaft accidents; 408 to miscellaneous underground accidents; 156 to accidents on the surface.

It will be seen that falls of ground were responsible for nearly 53 per cent. of the deaths.

Proportion of Preventable Accidents

Mines Inspector H. Walker (Scotland Division) refers to 21 deaths due to falls of side rib, or face, and expresses the opinion that 11 of them were entirely due to failure to set sprags and rances (props set against face). In this division there were 73 deaths due to falls of roof. The inspector says that five of them could have been prevented by the setting of temporary supports, two by the systematic setting of straps (boards resting on props) and four by a stricter observance of the timbering rules as laid down for the beds in which the accidents occurred. This means that of 94 deaths, 22 or nearly a quarter, were entirely preventable.

Mr. Walker emphasizes the fact that the question of adequate support being given to roof and sides is, after an efficient system has been arranged, one of discipline. Arriving at an efficient system suitable to the conditions existing in any coal bed is the duty of the manager of each mine, aided by the officials.

Having decided upon a system of support the inspector says that models of the method should be made and set up on the surface. Sketches he considers of little value, but full sized models that a miner could inspect at his leisure would show him exactly the manner in which the supports were to be set and advanced. However perfect the system, it is of small value unless compliance with it is rigidly enforced and this is where the necessity for strict discipline arises.

It would be thought that the man who was likely to be killed or injured would be the person most anxious to take steps to prevent an accident. A miner, however, *will* take risks and this factor must be taken into account. Inspection should be made at frequent intervals and visits to the various parts of the mine assigned to him should not be carried out by the official or any routine plan. Mr. Walker urges that uncertainty as to the time of the official's visit would prove beneficial and would result in a saving of life and limb where the system of support is rigidly enforced.

The inspector of the Northern Division, J. R. R. Wilson, regrets to have to repeat year after year that a large number of accidents should never have occurred. So long as men are reckless or thoughtless fatalities are bound to happen. In this division (Durham, Northumberland, etc.) accidents caused the loss of 218 lives. Of these the inspector says 93, a serious proportion, exceeding 42 per cent., might reasonably have been avoided.

Mr. Wilson reports: "There is a tendency to omit setting temporary supports, particularly when withdrawing timber. In this connection too there are frequent errors of judgment; and men seem to prefer when taking out timber to use a pick or an ax rather than a safety appliance."

Mr. Wilson does not hold the men solely blamable for this condition, for better discipline and supervision and a keener appreciation of the value of safety appliances by officials would certainly tend to reduce the number of accidents.

Accidents from falls of ground are commented upon by other British mine inspectors. J. Dyer Lewis (South Wales Division) declares that the only hope of reducing the number of accidents lies in the constant vigilance of officials and workmen. Mr. W. Walker (Midland and Southern Division) directs the attention of all concerned in the working of mines to the advantage of setting foresets or temporary supports wherever possible, until there is room for the permanent timber. He also impresses upon officials and workmen alike the necessity for stricter observance of timbering rules, as inspectors when visiting the collieries have frequently to call attention to places where the maximum prescribed distances have been exceeded.

Exclusive Use of Safety Lamps Advocated

In Scotland accidents due to accumulations of inflammable gas are numerous. Mr. H. Walker says that so long as they continue the ventilation of the mines cannot be considered as satisfactory. He advocates the universal use of safety lamps for, in his opinion, after their introduction a considerable proportion of such explosions would cease to occur. In Scotland miners and employers are much averse to the use of safety lamps. Apparently the opposition to them is so strong that it seems unlikely that they will be removed. The inspector says, therefore, that if naked lights are to continue in use adequate precautions must be taken. He would regard all mines as being equally dangerous and take steps to ventilate all holes in the roof, the face of all brushings, the high side of fast places; he would

use no lamps or lights other than safety lamps, when a new seam or district of a seam is being opened or when working near a whin or near a fault in the strata. Such precautions are simple, and the hope is expressed that the employers and also the miners who are liable to be injured should an explosion occur, will see that they are carried out.

In recent years more attention has been paid to ventilation and Mr. Wilson finds that frequent suggestions coupled with a readiness to take air samples for analysis have their effect upon the most backward officials. In such a district as South Wales, where large quantities of firedamp are daily drawn from the mines, Inspector Lewis says it is most essential that the volume of air in circulation should be sufficient to dilute and render the firedamp harmless.

The coal-dust problem is a subject of discussion wherever coal is extracted. In his report Mr. H. Walker points out that dry-stone walls or packs along the side of roadways form ready places for the settling of coal-dust. A liberal application from time to time of inert dust to the surfaces and crevices of such walls would, he says, prevent the settlement of more dust on and in them and at the same time furnish a guard against the danger latent in the dust already deposited there.

In Great Britain the local Mines Act requires that arrangements shall be made to prevent as far as possible the dust from the screen from entering the downcast shaft, and at all newly opened mines the preparation equipment must not be situated within 80 yd. of the shaft. The floor, roof and sides of the roads have to be systematically cleaned to prevent as far as possible accumulations of coal dust while systematic steps, such as watering, must be taken to prevent explosions of coal dust from occurring or, if they occur, from being carried along the roads. A precaution that came into operation on Jan. 1, 1917, requires that the cars shall be so constructed and maintained as to prevent, as far as practicable, coal dust from escaping through their sides, ends or floor.

The Lancashire inspector, A. D. Nicholson, refers to the difficulty experienced in keeping iron cars dustproof. This is causing some collieries to return to slightly improved types of wooden cars. He observes, however, that in deep and therefore warm mines this type of car is also difficult to keep dustproof.

In the Scotland report reference is made to five fatal firedamp explosions in which eight persons lost their lives. In connection with the most serious of these accidents the inspector says that "had obvious precautions been taken it would not have occurred." In the second case the fireboss was carrying both a naked light and a safety lamp when making an inspection. In the third and fourth cases the miners had gone into places which were fenced off. In the fifth case a brattice had been broken down by a fall, and two men were allowed to continue working before the brattice was rehung.

Commenting upon accidents with explosives, Inspector H. Walker says one course to adopt if a shot is not definitely heard to explode within a reasonable time is to regard it as a misfire and treat it accordingly. Another would be not to allow any person to have explosives in more than one hole at the same time when fuse is the medium through which the charge is fired. The inspector, in view of the numerous accidents, goes so far as to recommend that serious consideration be given to the prohibition of the use of fuse.

A man had his hip pierced by a nail and died. Inspector H. Walker says that too little attention is paid underground to the recovery of nails of all descriptions.

The use of glass bottles underground should be forbidden unless they are protected by suitable metal cases. In almost any mine, says the inspector, one can see broken bottles and when it is remembered that much traveling is done on hands and knees the danger is obvious. When nails are allowed to project from pieces of wood and when broken glass is strewn along the roads horses are subjected to serious hazards.

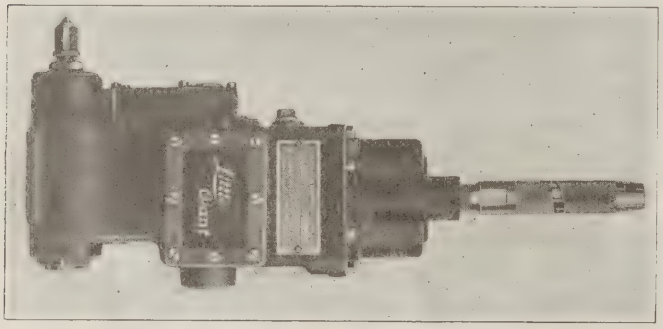
Many officials and workmen have been convicted of violation of the law. Among the more common contraventions of rules are those relating to matches and smoking.

Mr. Walker suggests that at each mine a committee of officials and workmen should be appointed. To it should be placed communicated details of every accident which occurs at the mine. It should have power to make recommendations for the prevention of similar accidents. Objection would doubtless be raised to the setting up of such committees on the ground that they would be likely to overstep their functions. If a good feeling is maintained and the object of their appointment is kept before them, the committees should do much to eliminate accidents. Perhaps some scheme of referring recommendations to an arbiter before they are put into effect would serve to make the operation of these committees more harmonious and beneficial.

Development of Lignite Mines in Greece Brought About by the War

With the stoppage of coal importation into Greece, it became absolutely necessary for that country to find some substitute, and the lignite mines at Kymi, Psachna, Aliveri and Oropes were exploited. These deposits were hitherto known, but inasmuch as the best Welsh and English coal could be obtained before the war as cheaply in Piræus as in the United States, it was not commercially practicable to work them. This unusual situation was due to the fact that steamers bound for Black Sea ports for grain brought out coal as ballast, discharging at Piræus.

More than 100,000 tons of lignite are said to have been mined from these deposits during 1917. A project is now afoot, which has the hearty approval of the Greek Government, to manufacture this lignite into briquets, which for many purposes will be equal, it is thought, to coal. It is hoped that through this means it may become possible to restore gas to Athens and Piræus. For cooking and heating purposes wood must now be used at very high prices, if one is unable to afford the charcoal which is vended from house to house in strictly limited amounts.



Erratum

In the issue of *Coal Age* for Dec. 12, 1918, page 1078, the sentence in the second column and seventh line below the small table reads: "The result was 35.86 per cent., or approximately 37 per cent. ash." Obviously this should have read "approximately 36 per cent. ash."

New Apparatus and Equipment

Little Giant Corner Drills

The Little Giant corner or close quarter drill, manufactured by the Chicago Pneumatic Tool Co., of Chicago, Ill., has been designed to overcome the objection arising from the intermittent action of ratchet levers in the rotation of the spindle. In this drill steady, uninterrupted revolution of the drill spindle is accomplished by means of a train of gears, thus retaining all the advantages of the ratchet type and permitting the drill

LITTLE GIANT CLOSE-QUARTER DRILL

to be used in the same narrow space, or within $1\frac{7}{16}$ in. of the end wall or corner.

In this drill the power of the motor is transmitted to the spindle without vibration, resulting in a steady, even pull with minimum wear and tear on the machine itself.

In the stub tooth gears which are employed, the root of the gear tooth is much thicker than in the standard involute tooth. The tooth itself is shorter, hence it will withstand a harder pull. The special alloy steel used in these gears makes them highly resistant to wear.

Removable Truck Safety Switchboard Units

The removable truck-type safety switchboard units here shown are eminently fitted for use in electric power plants. They can be obtained for the control of generator, motor and feeder circuits, and are particularly adapted to plants where electrical distribution is made from a centrally located distribution center. The construction is such that extensions can be readily effected or the units moved to other locations to meet new or changed conditions. All current-carrying parts are inclosed, and the opportunity for an operator to come in contact with the circuit is practically eliminated.

A spare removable unit can be used to reduce the time of shutdown for inspection or repair. Busbars need not be killed, disconnecting switches need not be opened, leads and small wiring are not disturbed. The oil switches, buses and all live parts are placed in compartments. This tends to reduce fire hazard and limits disturbances to a single point.

The stationary member of the removable truck switchboard carries current and potential buses with their disconnecting switch studs and barriers between the current studs to prevent accidental contact by any one who enters the compartment. The rear end of the current disconnecting switch studs runs to buses and incoming or outgoing leads; the potential bus wires to small contact studs near the top of the compartment. The side walls are provided with hand holes, so that the busbars and bus wires can be continued from unit to unit. On the exposed walls of the end units these openings can be closed by removable covers. Access to the rear of a compartment can be had by means of hinged sheet-steel doors provided with means for padlocking in the closed position.

The removable truck is mounted on wheels. The forepart carries a sheet-steel panel on which is mounted the instruments, meters, oil switches or other appliances usually employed on the ordinary slate switchboard panel. The current transformers are mounted on steel brackets back of the instrument panel. The rear of the truck carries the movable parts of the disconnecting switches, the potential transformers and small wire accessories. To center the truck and to assist in placing it in or removing it from a compartment, rails fastened to the side of the compartments are furnished. The oil switches, instruments, meters, transformers, etc., are removed from the installation by wheeling out the truck.

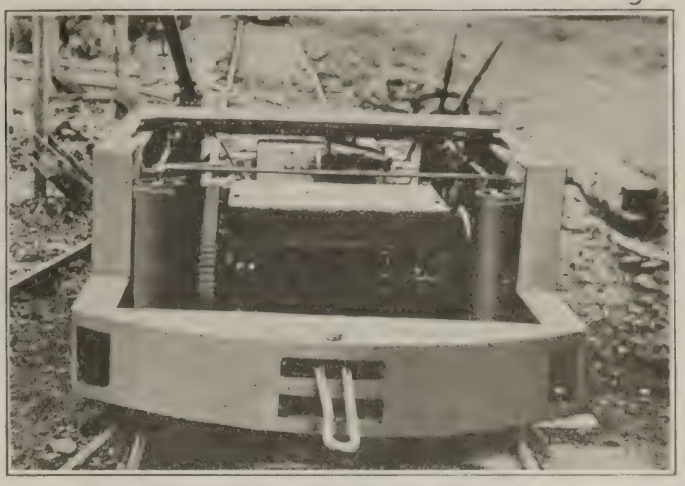
In order to remove or replace a switch unit, the oil switch must be opened and therefore the load disconnected. This is provided for by an interlock attached to the oil switch operating toggle, which engages cast lugs on the walls of the stationary unit. With the oil

REMOVABLE TRUCK SWITCHBOARD UNITS

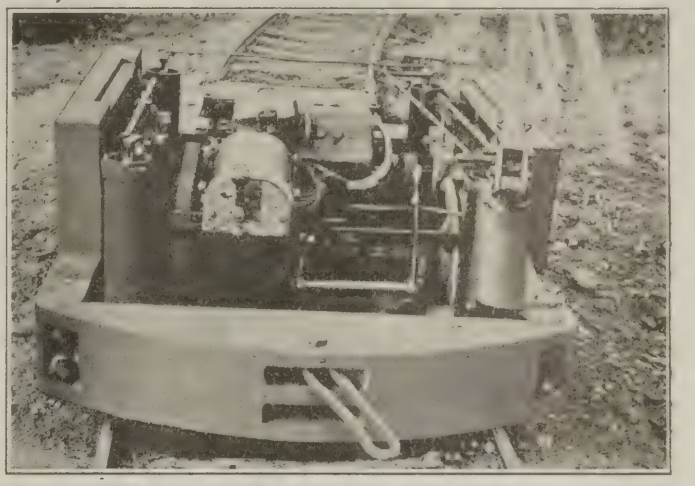
switch closed it is impossible to remove or insert the truck. The value of this feature is self-evident.

These panels are being regularly manufactured in a variety of styles and capacities and vary in capacity from the smallest up to and including 1200 amp. They are designed to operate at voltages up to 15,000. In the larger sizes the housings are usually of reinforced concrete, and all capacities are designed for use with either solenoid or manually-operated oil circuit breakers. These units are made by the General Electric Co.

New Type of Mine Motor



By D. I. Wheeler
Cleveland, Ohio

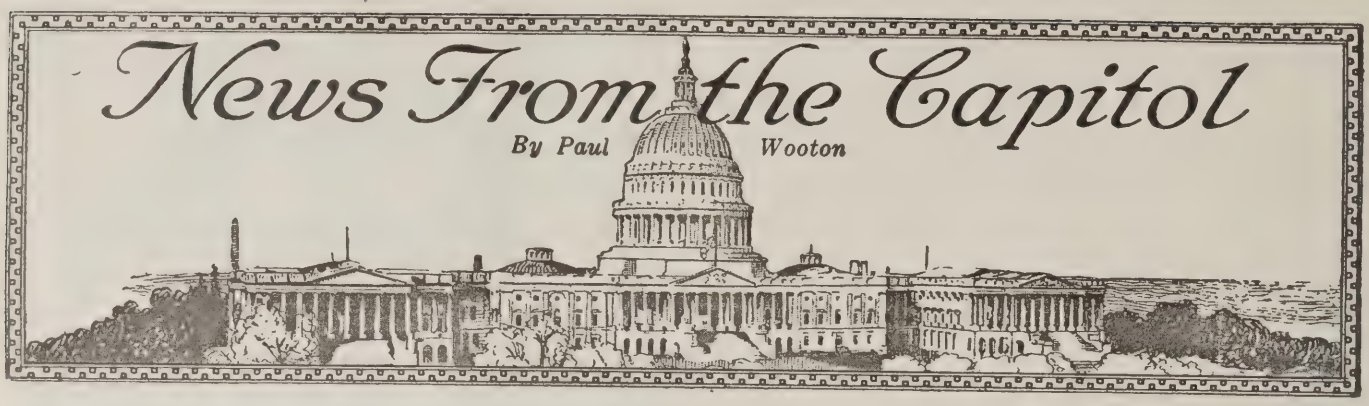


A novel type of coal-hauling motor has been developed and is now being started toward quantity production by the Nelsonville Electric Co., of Nelsonville, Ohio. The striking feature of this locomotive, which is shown in the accompanying photographs, is its extreme lowness, the total height over the rails, exclusive of trolley, being only 29½ in. The same dimension as to height is to be maintained on all motors of from three to ten tons, the point being, of course, that this tractor can be used in many low-vein drifts where a larger type could not gain access. The hauling capacity is equal to or greater than that of more cumbersome machines, which are often useless where the headroom is low.

In eliminating height, the Nelsonville people have gained in simplicity of construction and efficiency of operation. The motive power consists of an especially designed Western Electric type motor built by the General Electric Co. The maximum speed of this motor is 600 r.p.m. It is operated by a compact G. E. controller mounted horizontally on the frame. The motor is mounted exactly over the center of the wheelbase and the power is transmitted directly to each axle by a symmetrical arrangement of two Morse rocker joint silent chain drives, one being at each end of the armature shaft. The advantage of this type of transmission is that a driving efficiency of 99 per cent. is attained and the noise and friction of gear trains are eliminated.

This arrangement also cuts down the number of parts. The machine is therefore subject to much less trouble, and is more durable. The wheels are 20 in. in diameter, with a wheelbase of about 24 in. This short wheelbase further carries out the idea of reducing room necessary for operation in small rooms or short turns. The maximum speed of the machine is governed by a three to one reduction through the chain transmission, and is between 11 and 12 miles per hour.

In addition to the advantages named above, other distinguishing features of this locomotive are the extremely simple oiling device for the axle, by means of which oil and waste can be easily replaced; accessibility of working parts; and a simple and easily operated braking device.



TWO VIEWS OF MOTOR MOUNTED ON MINE HAULING CAR

It would seem that this new locomotive has such merit that the manufacturer is justified in the extensive plans which are rapidly being carried out for the production of these low-type motors on a large scale.

NOTE THE EXTREME LOWNESS OF THIS NEW TYPE OF COAL-HAULING MOTOR

United States Had Huge Mineral Output in 1917

The value of the minerals produced in the United States in 1917, according to the United States Geological Survey, Department of the Interior, was $5,010,948,000, an increase of $1,496,976,000, or about 43 per cent. over the former record—$3,513,972,000—established in 1916. The blast-furnace products (pig iron and ferroalloys), copper, coal and petroleum contributed 74 per cent. of the total value of minerals produced and 88 per cent. of the increase in 1917.

The metals established a new record in 1917, being valued at nearly $2,092,000,000 and representing 42 per cent. of the total value of the mineral product. They showed an increase of about $471,316,000, or 29 per cent. over the $1,620,508,000 reported for 1916. The blast-furnace products contributed nearly 90 per cent. of the total increase. Increases were also made in the value of aluminum, copper, lead and silver, but decreases were recorded in the value of gold and zinc.

The value of the nonmetallic products in 1917 was 58 per cent. of the value of all minerals produced, increasing $1,010,459,000, or nearly 54 per cent., from the former record of $1,878,464,000 in 1916 to $2,888,923,000 in 1917. Of this total increase coal alone represented nearly 66 per cent., and coal and petroleum combined contributed about 85 per cent.

Fuel Administration's Work Slowing Up

Visitors to the Fuel Administration these days are reminded that the war is over. The building which only a few weeks ago was a veritable beehive is strangely quiet. Half of the rooms apparently are not in use. The mildness of the winter and the unimportance of production and transportation problems, as compared with those of a year ago, have been important factors in the falling off of the administration's work. Even anthracite seems to be overcoming its difficulties, and the men who were being held to handle that situation have little to do.

While there is no shortage of bituminous coal reported from any point, it is the intention of the distributing section to continue work through the winter as distribution problems continue to arise in large number.

It is stated that in the United States there are known deposits of lignite aggregating 150,000 square miles in extent, containing about 100 billion tons of this fuel.

Railroad Administration Would Abolish Garfield Coal Prices

A determined effort is being made by the Railroad Administration, it is understood, to secure the abandonment of the coal price schedule. While most of the officials at the Fuel Administration believe it would be a great mistake to abandon prices before the end of the coal year, there is uncertainty as to what Dr. Garfield will do in this regard. Dr. Garfield has the reputation of listening patiently to all that his lieutenants have to say and then going ahead according to his own ideas. As it is possible that he may handle the price schedule in that way, few would be surprised to see the prices abandoned Feb. 1, and some think that such action may be taken even as early as Jan. 1. No explanation is forthcoming, however, as to how justice would be done to those whom the Government has forced to stock up on inferior coal, which would be a drug in their bins.

Upholds Rates on Pea and Slack

Rates on pea and slack coal from the Walsenburg district, Colorado, to points in Kansas, on the Atchison, Topeka and Santa Fe Railway, have been upheld by the Interstate Commerce Commission. The rates were attacked by the Alliance Coal and Coke Company.

Warrior River Coal Transportation

An official statement regarding the Warrior River barge line which will engage entirely in the transportation of coal from the Alabama fields to tidewater at New Orleans and Mobile, was issued Dec. 14 by the Railroad Administration. It reads as follows:

"Plans have been completed for providing new equipment under the jurisdiction of the United States Railroad Administration for service on the Black Warrior River.

"There are two distinct services: One from Cordova (near Birmingham, Ala.) to New Orleans, and the other from Cordova to Mobile, Ala. The Cordova-New Orleans route is partly river and partly sheltered Gulf operation. To provide for the New Orleans service self-propelled steel barges 275 ft. long, 49 ft. extreme beam, and 10 ft. depth, with triple expansion engines (2) 400 hp. each, and water tube boilers of the express type, are proposed. Such boats will carry 1800 tons of coal on a 7½ ft. draft, and the proposed design contemplates a cubic capacity of about 500 tons for merchandise freight. The estimated cost of such a self-propelled steel barge is about $250,000, and in its construction

about 500 tons of steel will be required. Four such vessels, with annual capacity of 175,000 tons, will be provided.

"For the enlarged Mobile service, it is proposed to construct 20 wooden barges of approximately the type now used on the river, and three steel towboats with approximately 400 hp. each. The estimated cost of each towboat is $160,000 and the 20 wooden barges can be constructed for $120,000.

"This represents a total expenditure of $1,600,000 for the Warrior River system to provide an increased annual coal movement of 375,000 tons.

Lignite Bill Not To Receive Immediate Consideration in House

An effort to bring up the lignite bill in the House for immediate consideration has failed. The rules committee agreed to order its immediate consideration, provided the committee on mines and mining should make a unanimous request to that effect. A single member of the committee on mines and mining refused to concur, thereby making it necessary for the bill to take its regular place, which is far down on the congested calendar.

Questions Fuel Administrator's Power

An interesting question has been raised by the following resolution, which has been passed by the Senate:

"Resolved, That the fuel administrator for the District of Columbia be directed to inform the Senate what steps he is taking to enforce the order made fixing the maximum charge for putting in or storing coal at 75c. a ton in the District of Columbia, and if no steps are being taken to enforce said order to inform the Senate why this is not being done and by what authority of law was said order issued."

The resolution was introduced by Senator Jones, of Washington. It brought forth the following comment from Senator Reed, of Missouri:

"I have no objection to asking for the information, if it is done in a form which does not appear to involve the sanction of the Senate to this order. The fuel administrator in Washington, of course, has just as much authority to fix the price for putting in coal as he has to fix the price of any man's wages, and it is time that this assumption of arbitrary power should cease everywhere in the United States."

Praises Volunteers Who Manned Coalers

Certificates of honor have been issued by the Shipping Board to the volunteers who stepped into the breach last spring and made it possible to man the vessels in the New England coal trade. An official statement in regard to the matter is as follows:

When the great German drive of last spring was in full swing, and the war industries of New England were clamoring for coal, in order that clothing and blankets and bullets for the American forces in France might be turned out on schedule, the U. S. Shipping Board called for volunteers to serve in the fireroom and deck crews of the steamers carrying coal from Virginia to New England ports.

Numbers of young men who had entered the Merchant Marine training service with the hope of getting into the crews of ships going overseas, put their personal wishes aside and volunteered to help man the coalers. It was hard, cold, disagreeable work, but it was done so effectively by these volunteers that records of efficiency were made by the coal-carrying ships, and the New England war industries were enabled to keep their fires and their production up to the limit necessary to maintain an uninterrupted output.

The Shipping Board announces that it has recognized the spirit of patriotic self-sacrifice shown by the Merchant Marine volunteers who manned the coalers in that period of stress, and has ordered that certificates of honor be issued to them. Every man who has served three months on board a New England coaler will get one of these marks of distinction.

Zone M-2 Has Been Enlarged

Coal produced in the Logan and Kanawha districts may now move to tidewater via the Chesapeake & Ohio R.R. This was made possible by the enlargement of consuming zone M-2. Previous modifications affecting these districts have allowed for westward shipments only.

Increased Output of Domestic Sizes of Anthracite

Production of prepared sizes of anthracite, during the week ended Dec. 14, exceeded the production of any week since that ended Oct. 5. The output of that character of coal was 1,197,079 tons. Total production for the week of Dec. 14 was 1,923,625 tons, an increase of nearly 7 per cent. over that of the week preceding.

Coal Loadings Ahead of Last Year

Including the week ended Dec. 14, the loading of coal cars exceeded the performance during the same period of 1917 by 546,766 cars. During the week ended Dec. 14, the number of cars loaded, as well as those during the corresponding week of 1917, are shown as follows:

	1918	1917
Total cars bituminous	181,823	147,631
Total cars anthracite	36,401	31,656
Total cars lignite	4,094	4,653
Grand total all cars coal	222,318	183,940

Brief Washington Notes

Exporters of coal and coke no longer are required to file Form X-6 with the War Trade Board.

Russell Hastings, of Boston, who has been in charge for the Fuel Administration of bituminous coal distribution, as related to public utilities, has resigned.

Lake shipments of cargo coal in 1918 were 28,153,317 tons, according to the Geological Survey. The tonnage is the greatest ever carried in one season.

One of the war accomplishments of the Bureau of Mines, which will be a peace-time asset to the country, is a change in the design of marine boilers, so that the coal heretofore necessary to propel the ships for six miles is now sufficient to carry them seven miles.

Coal exported during the fiscal year ended June 30, totaled 25,894,166 tons. The growth in the amount of coal exported is shown by comparing it with the exports of the corresponding period ended June 30, 1914, when exports were 19,664,080 tons.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The recent United Mine Workers election is the principal matter of interest. Rumors have spread that John Walker of Illinois has carried the anthracite field against Frank J. Hayes, the past president of the United Mine Workers. Ellis Searles, the editor of the *United Mine Workers' Journal*, recently stated that Frank J. Hayes had a majority of more than 40,000 votes and so would be reëlected by a majority of 50,000 to 60,000.

An announcement has been made at the office of District No. 1, United Mine Workers of America, that John T. Dempsey, former president of the district since 1911, who, two months ago, resigned has been appointed as a representative of the international body throughout the anthracite region. His work will be the organization of new locals and the building up of those now in existence, and his new office will take him into his old district, No. 1, as well as Nos. 7 and 9.

WANT THEM TO WORK EVERY DAY BUT CHRISTMAS

The Fuel Administration on Dec. 21 issued an appeal to the anthracite mine workers to work industriously every week-day this week except Christmas Day, so as to make amends for the loss of output naturally arising from the outbreak of influenza and the time lost for jollification over the armistice.

For the first time Mexicans have been imported into the Hazleton region. Their introduction into the northern anthracite field at Carbondale made a great deal of trouble. A similar complaint to that made in the northern field will probably be made at Hazleton. On Dec. 17 the George B. Markle Coal Co., unable to maintain production, brought 100 Mexican laborers into the district to work in its mines.

From West Virginia comes the information that the coal operators of northern West Virginia and the United Mine Workers of the same area reached an agreement Tuesday week, Dec. 17, which is said to be satisfactory to all concerned. It has been ratified by the directors of the Northern West Virginia Coal Operators' Association.

FAIRMONTERS MAKE SETTLEMENT OF DIFFERENCES

At the first conference of the operating committee of the association the following representatives of operating concerns were present: A. C. Beeson, chairman, C. H. Tarleton, J. M. Wolfe, Brooks Fleming, Jr., J. A. Clark, Jr., of Fairmont; C. J. Ryan, of Hepzibah; Everett Drennen, of Elkins; J. M. Orr, of Clarksburg; A. L. Hamilton, of Pittsburgh, and L. J. Sandridge, of Meriden. The representatives of the United Mine Workers of America were: Robert H. Harlin, an international representative, of Indianapolis; C. F. Kenney and Fred Mooney, of Charleston, president and secretary respectively of District No. 17; Francis Drumm and William J. Trickett, of Cumberland, president and secretary respectively of District No. 16; Joe Loftis, of Cumberland, and Sam Ballentyne, of Albion, Iowa, members of the international board. The agreement follows:

Memorandum of agreement entered into at Fairmont, W. Va., Dec. 17, 1918, by the coal operators of the territory covered by the Northern West Virginia Coal Operators' Association and by the United Mine Workers of America of District No. 17.

It is specifically and mutually agreed that the agreement entered into by the operators and the United Mine Workers of America at Fairmont on Aug. 31, 1918, shall be the basic thick-seam agreement for the territory embraced by the Northern West Virginia Coal Operators' Association; and that the agreement entered into by the operators and the United Mine Workers of America at Fairmont on Sept. 7, 1918, shall be the basic thin-seam agreement for the same territory, and further that no other agreement shall be agreed to by the organization and any individual operator in the above specified territory during the period of the above-mentioned agreements.

At mines where the mining or day-wage rates prevailing are higher than those prescribed in these present basic scales, such rates shall exist during the period of the present basic agreement, unless both operator and miners agree to a change in such rates in harmony with basic rates.

It is further agreed that at the termination of the present agreement, a basic uniform scale for the thick and thin seams respectively, and for day rates will be adopted for all operations in the above-specified districts.

MONTHLY MEN GET THEIR $1.40 A DAY RISE

The 2000 employees of the New River Co. reached an understanding with that concern on Dec. 12 and, in consequence, the strike which has interfered with production since Dec. 3 was declared off and the men returned to work.

The terms of the agreement reached may be summarized as follows:

1. Monthly men, except those exempted by the United States Fuel Administration, shall be paid the $1.40 per day increase on the basis of 25 days per month, when employed full time, and the claim for the difference between 25 and 30 days shall be subject to review and to the decision of a special umpire.
2. The decision of the special umpire with reference to trappers' wages shall be accepted.
3. The decision of the special umpire on Sam Oliver's case shall be accepted as decided and shall apply to men employed previous to Apr. 16, 1917.
4. The car-pushing case shall be reopened by joint request of the operators and members' representatives.
5. Inasmuch as the decision of the special umpire in the 60c. case does not apply to monthly men, it is agreed that any monthly man feeling himself aggrieved in this matter may have his question submitted to the special umpire for decision.

The decision regarding those monthly men, who are not exempted by the United States Fuel Administration is as follows:

"The contention of the miners that the Washington wage advance should be applied to day and monthly men in the New River field is sustained, and all day and monthly men, except mine managers, top and bottom bosses, weigh bosses, firebosses and head mechanics shall be given the increase provided for in the Washington agreement; namely, $1.40 per day. The coal operators who have received since Nov. 1, 45c. a ton increase in the selling price of their coal for the purpose of absorbing the Washington advance, will be required under this decision to pay all back money due the men affected as herein defined."

MEN OF ROARING CREEK FIELD GO BACK TO WORK

After being on strike for about 10 days the striking miners of the Roaring Creek field were induced to return to work by John P. White, former international president of the United Mine Workers, who visited the headquarters of District 16 at Cumberland on Dec. 8. White urged the miners to return to work pending an adjustment of their grievances, which had to do with a construction of the terms of the Freeport scale agreement.

Short time in the bituminous mines is a rapidly spreading epidemic. The most recent report of the Geological Survey appears 19 days earlier than the date of our publication and so does not represent the conditions of the date of issue. The percentage of loss of time due to no market had 19 days ago risen to 6.0. The week before it was 5.7. The strike and labor shortage loss had risen to 7.2 per cent., having been 6.1 the week before. Doubtless next week's report, which will cover up to Dec. 14, will show more mines out of work for lack of orders.

A NEW YEAR'S GREETING

FATHER TIME :- TAKE THESE BONDS. PART OF THEM WERE LEFT ME BY MY FATHER. 1917, AND PART I HAVE BOUGHT MYSELF. KEEP THEM AND ADD TO THEM, FOR SHOULD YOU NEED A FRIEND YOU COULD NOT FIND A BETTER.

Friends and Fellow Workers:

I wish you a Happy New Year! Many Happy New Years, each happier than the one before.

During the past two years we have all been buying Liberty Bonds, so we have something put aside for a rainy day. Let us keep our Government bonds till we really need to use them; at any time we may have sickness at home, or a hunting accident or even a slack run at the mine.

Let us buy more bonds when they are offered to us, or even before a new issue is offered—for bonds of previous issues are always obtainable.

Remember, it is always patriotic to furnish the capital by which necessary and permanent work is done, whether the completed work takes the form of railroads, mines, factories, ships or houses. But the man with small funds can rarely run the risk that goes with such an investment. Only a well-to-do man can afford to risk his money in that way, trusting to balance his heavy losses by great gains. So when you invest your money, stick to savings stamps and national, state or city bonds, or put your money in banks where you will be sure of both capital and interest.

By such savings you will secure a happy future and growing prosperity year by year. Again wishing you a Happy New Year, I remain,

Yours cordially,

EDITORIALS

Railroads Should Deliver Clean Cars

GOVERNMENT ownership has one advantage. When the Government runs a plant it can appeal to patriotism to get its behests attended to. It can bring pressure which, applied by any other agency, would be resisted.

The railroads for years have been imposed upon by those shippers who, receiving low-grade material, were indifferent as to whether they unloaded it all or left a percentage in the car. Especially is the temptation strong during the winter, when much of the material is received frozen and men are hard to find.

The shipper would rather leave frozen sand, ashes, gravel, manure, sawdust or low-grade clay in the car than diligently dig it out. The railroad, of course, could see to it that the cars were cleaned did not a fall of snow cover up the floor of the car. Frequently no one knows the condition of the car till the trimmers at the tipple get busy with their shovels and brooms.

Then the cry goes out loud and persistently for the mine foreman: "Shall we clean this car and meanwhile shut down the mine or let it through or even load it up without cleaning?" If cars are badly needed and the railroad pressing for the use of all equipment, then there is a great likelihood that the car will be filled without cleaning or, if too dirty, cleaned at much trouble, delay and expense.

Sometimes several men are busy at such work, the tipple force discovering the offending car long before it is run down under the loading chute, or to some point where the closeness of the tracks makes cleaning impossible. If the car is run below the tipple, the railroad has much trouble switching it out of the train to some place where the local section gang can in its few spare hours find time to clean it out.

Why should not the United States Railroad Administration memorialize the shipper of low-grade material and make him cease his abuse of the rights of the railroad and other shippers? The opportunity to bring the shipper to a better habit and conscience in this matter is right now, when the railroads and the nation are one, and he who inconveniences the one directly defrauds the other.

The railroad itself is often somewhat to blame, for its own men are sometimes careless in unloading cars of ballast and leave much material in the bottom of the car. The exigencies of railroad operation sometimes furnish an insufficient excuse for neglect of this kind.

Coal May Oust Gasoline for Motor Cars

OPERATORS of coal mines can look forward to large changes in the coal industry in a few years. The British *Daily Review of the Foreign Press* gives a brief notice based on an article that appeared in the well-known Swiss paper, the *Schweizerische Bauzeitung*. Superficially it does not seem to concern the coal operator, headed as it is "Acetylene as a Substitute for Benzol," followed by the statement of Dr. Grossmann, of Zurich, who in 1915 and the year following pointed out that "acetylene might be used as a substitute for benzene (and therefore for gasoline) in driving motor cars."

When we remember that calcium carbide, the recognized source of acetylene, is made by subjecting coke and lime to the high temperature of an electric furnace, we begin dimly to see where the coal industry enters into the problem; for acetylene is, speaking broadly, a byproduct of coal. It may well prove to be an important after-product of the coke output of the byproduct coke oven.

But always it must be remembered, as Dr. Grossmann points out, that acetylene explodes somewhat too rapidly to be a suitable source of power; that alone, and in its mixture with air, it will explode at a pressure of 30 pounds per square inch and that, when the combustion in the motor is imperfect, soot and acid combustion products will rapidly form. To lengthen the period of explosion water, steam, benzene, benzol, gasoline, pitch and naphthalene may be added, but the two first—water and steam—give no energy and will absorb some of the power. The explosibility under pressure can be cured by the introduction of acetone in the storage tank. Of course, the difficulty about inefficient combustion can readily be cured. Acetylene may be either stored in cylinders or generated on the car.

The problem is interesting. At present it seems visonary, but who can deny that coal may conceivably take over most of the work now done by petroleum? Kerosene and paraffin are rapidly losing their character as illuminants. Acetylene, coal gas and electricity are ousting them from their former place as sources of light, all these three illuminants being manufactured with the aid of coal. Maybe the power use of petroleum byproducts will also come to an end, and then little will be left as *rôle* for petroleum other than to serve as a lubricant; and even that function seems threatened by a substitute made from coal—namely, anthracene oil.

Tithing America for the World's Benefit

ONE OF our contemporaries is urging that as "the productive capacity of the United States is 10 per cent. in excess of its consumption requirements, 10 per cent. of our total production must be sold in foreign markets to provide continuous employment for all our productive agencies." If we are going to sell 10 per cent. more than we buy we must extend credit for that 10 per cent., and as interest will accrue on that credit we must not only give a credit of 10 per cent. of each output yearly, should we supply so much to foreign buyers, but extend a credit also that will allow

the foreigner to pay his interest indebtedness by new credits instead of with goods.

We produce, at present, roughly 40 billion dollars worth of goods yearly. If we send 10 per cent. of our product abroad, that will be four billion dollars of produce per annum. If we will not receive in products either the capital or interest on this impressive sum, how long will it take to pile up a bill which, to pay, will bankrupt the world?

We cannot sell, sell, sell and never buy. We cannot work for the world unless we take our pay in the work of the world. Thoughtless Americans urge on us an independent America that buys nothing. How can such an America be, except it is a self-contained America that not only buys nothing but also sells nothing? The sign of export trade is foreign goods in our market, just as much as it is our goods in a foreign market.

We shall for a while sell Europe more than we buy, because of her present necessities. We shall continue for a few years to add to the indebtedness of the non-American population of the world. Well and good. But the process before long must end. The lender must soon get more than he gives to the borrower or lose at least the interest on his loan.

He who works for the foreigner slaves for the foreigner unless the foreigner pays him with labor and goods for his services. Why are we so keen to ship abroad? That which we can produce with a minimum of labor we can profitably ship; that which it perplexes us to produce, and which the foreigner can manufacture easily, let us buy from him unless we fear there will sooner or later be a war between us. Then it is best not to be dependent in any way on our opponent.

Some day we may be as ready to buy of France as Pennsylvania is willing to buy of New York. What does it profit us to keep up these national lines unless thereby the safety of our homes and our hearths is inperilled?

Isolated Plant Versus Purchased Power

REAMS OF discussion have been printed on the subject of the relative profit in the purchase or generation of power, all based on conditions as they are. We are going to be bold and discuss them on conditions as they ought to be. Most of the isolated plants are using good coal under their boilers. They ought not to be. The bony coal, pyrite and slack should be used for that purpose, but many plants have no provision for crushing and burning the bone and the pyrite. Many operators have planned the use of fine coal and have been obliged to use the coarser material because the equipment provided would not burn fine coal to the best advantage.

For these reasons the isolated plant at the mine is apt to burn coal which is distinctly superior to that furnished to the central power station.

It should take advantage of the fact that the poorer coal produced at the mine will net the operator little or nothing and can be profitably used to make steam if it is utilized at the point of origin.

If the refuse of the seam is large and is to be used, it must be used at the isolated plant. It will not do to ship it a long distance, for it is not worth the freightage. The isolated plant will therefore be an economizer of fuel whenever we have arrived at the point that will make us disposed to use these mine wastes.

Some operators already use such coal and find the use pays. The great difficulty of the isolated plant is that it costs too much money to run because of the cost of engaging a competent mechanical engineer, but there is no question that if power is generated out of the mine waste the engineer will justify his salary in a saving of coal used, in the maintenance of the line work and conductors inside and outside, and in the running of the machinery.

In this way eventually the question "Isolated Plants Versus Purchased Power" will take on a new phase. But still greater will be the difference if we make coke or semi-coke at the mines and obtain heat and power from the gases thus formed. For years boilers have been operated by heat from beehive coke ovens. Engines may be run from power generated by the gas from by-product ovens or from steam raised in boilers that are heated by byproduct-oven gas. In these cases we are, or shall be, faced with the problem of wasting the gas or using it in an isolated plant or at a central station plant located at the mines.

It must be remembered, however, that in low-temperature distillation as it has quite usually been conducted there has been no heat available for other uses. It may be expected that in the future the losses of heat in the low-temperature distillation process will be so reduced that there will be a disposable balance of which an isolated plant could make good use.

Effect of War on Labor

THE war just ended will not in itself promote the real interests of laboring men. It has made many cripples. These men will not have the productive ability that they enjoyed before the war, yet they must be permitted to consume as much, and most of us feel they should be so provided for that they will be able to consume a great deal more than they did before the war commenced. Consumption cannot safely be brought too close to production, and as the consumption of some individuals will not be balanced by their own production, every one is bound to receive less in values even though expressed in money they will doubtless receive more.

There is a disposition to believe that there will be a shortage of labor because many men have died from influenza or been killed by bullets and shrapnel; but concurrently the consumption of the products of labor will be less because of the mortality, and that will reduce the productive demand.

The only hope to be derived from the war is that it will stimulate reactions in the public mind which will increase production and thus make an increased consumption of products possible. If the labor records made in the bellum days are continued in the post-bellum days, we may look for a general increase in prosperity. The more we make, the more we have to distribute or to use for the facilitating of further production.

It is possible that the abilities of the worker and of the managements of our plants have been stretched by the war to such a point as to give the stretch a permanent set. If we, each and all, produce a little more than before, we shall more than overcome the handicap that the war has placed on us.

DISCUSSION BY READERS

Iron vs. Wood Mine Cars

Letter No. 6—Three years' experience with an allsteel car, enables me to compare this with my previous experience with wooden cars, and prompts me to say that I very much prefer the old-style wooden car for mine use.

In the first place, the iron car is expensive to install and to operate. The use of iron cars in mines also increases the cost of upkeep of the track. When an iron car jumps the track it generally breaks two or three ties and, perhaps, bends or breaks the rails.

A small company seldom possesses the kind of equipment required to repair iron cars that are damaged in a wreck. There is no arc-welding apparatus; and, without these extra appliances, the work of repair is slow and the car remains out of service too long.

On the other hand, wooden cars are less expensive to build, and the necessary material can generally be secured near at hand. Most mines are located where good white-oak timber can be obtained at a reasonable cost. Wooden cars are more pliable and, for that reason, are not so hard on the track. The repair of wooden cars is a comparatively simple matter and requires no apparatus except what is ordinarily found in a blacksmith or machine shop at mines. Finally, the time required to repair a wooden car is less than for an iron one.

———, Utah. MINE FOREMAN.

Cost of Upkeep of Mine Cars

Letter No. 1—I was glad to see the suggestion of a correspondent in *Coal Age*, Nov. 14, p. 918, in regard to the need of keeping an accurate account of the cost of repairs on mine cars. He drew particular attention to the difference, in cost, between haphazard and systematic methods of making such repairs.

To my mind, cost-accounting is a very important item in the operation of a mine and one that has been too long neglected. Many coal operators view the making of repairs as a necessary evil. Sometimes repairs are needed so often that they are an unnecessary evil. The frequency of repairs may be due to a poor type of mechanical construction.

ECONOMY IN SELECTING RIGHT KIND OF CAR

Today, when there are many different types of mine cars manufactured, the importance of ascertaining what types are more economical in actual use is greater than ever before. It is my experience that most coal operators pay large repair bills as a matter of necessity, without investigating the saving that might be effected by a change of equipment.

One notable exception to this rule that came to my notice, recently, is that of a large concern operating about a thousand cars in their mines. They concluded that it cost them $5000 a year to make the necessary repairs due to the breaking of end-gates alone, and not considering other breakage resulting from the inherent weakness of the type of car they were using. Judging from the condition of the cars I have seen in that mine, the average cost of $5 per car, per annum, for repairs appears to me as being reasonably low. I shall be glad to learn of other operators who have kept an accurate account of this item.

Manufacturers are now putting on the market several styles of dumps and cages for turning a solid car completely over in dumping, similar to the method of handling railroad cars on the big coal piers. A number of large operators, in various parts of the country, have installed these cars and dumps at their mines. They appear to be firmly convinced that this is an easy method of handling mine cars on the tipple. The car is handled much more gently when being dumped. The elimination of the end-gate, in a solid car, provides a type of construction that is stronger and more durable, and the cost of repairs is greatly reduced, being next to nothing. SHELDON SMILLIE.

Pittsburgh, Penn.

Letter No. 2—Referring to the matter of keeping cost-sheets, showing the amount paid for repairs to mine cars, permit me to say that these sheets mean nothing if they are not kept accurately and made to show in detail what repairs are made and how often.

The matter of cost accounting, in repair work at our mine, has been a careful study with me for some time past. I have found that, in order to get results, one needs a large ledger, having the pages so ruled that the cost of labor and material expended on each car will appear in its proper column. Every car in the mine should be branded with its number, and the repairs made on each car should be entered against that number, in the ledger.

NATURE OF REPAIRS MADE SHOULD BE NOTED

In addition to noting the cost of labor and material and the date of repairs made on each car, there should be room to specify the nature of the repairs. One would be surprised to see how simple this data is to keep, when it is properly arranged, and to realize its importance in determining what improvements can be made in different features that will reduce the cost of future repairs. In other words, the weak points in the construction of cars are clearly shown by studying the ledger.

There is another feature of this cost accounting that is worthy of note. Repair men take more pains to do their work thoroughly. They realize that it looks bad to have a car returned too often to the shop for repairs. The natural conclusion is that the work was not thoroughly done, and they naturally want to avoid such a showing.

Wagon repairs should only be analyzed from a study of the ledger once a year. As mentioned previously, the

showing on the ledger will indicate clearly the style or kind of equipment that is most economical in service. This information is of particular importance in showing the advantage of certian kinds of car wheels, in respect to their size, bearings and lubrication.

Once every month there should be a competent man stationed on the tipple, with instructions to inspect each car as it comes out of the mine. All defective cars should be promptly turned in to the shop for repairs, before being again sent into the mine. This practice will be found to avoid many wrecks that would otherwise occur. There is no economy in postponing the making of needed repairs. Every practical mining man will agree with this statement. It is simply following out the old adage, "a stitch in time saves nine."

Cost Accounting in Mine Haulage

Letter No. 2—Referring to the suggestion of "Progressive," *Coal Age*, Nov. 7, p. 876, in regard to motor-haulage costs, I regret being unable to give definite figures, or to furnish a chart for estimating the costs in this branch of coal mining. I will, however, consider briefly the items that enter into the operating costs of haulage by motor. In all mine haulage, the items of cost fall under two general heads; namely, Operating Costs and Costs of Maintenance. I will attempt to specify these items and classify them under these heads.

Whether the power, in mine haulage, is supplied by a local branch or a public service company, it appears as a monthly operating charge, estimated as kilowatt hours, based on the horsepower, consumed in the operation of the mine. Where the power is furnished by a private or local plant, the charge for the same is based on the operating expenses and overhead charges of the power plant.

In other words, the power plant furnishing the power to the mine is an entirely separate and distinct operation, and performs this service at a reasonable charge, which is estimated in the same manner as a public service plant. It is, of course, the duty of a power plant to deliver power to the mine and, therefore, all transmission lines from the plant to the mine entrance belong to and must be maintained by the power plant. Transmission lines within the mine are the property of the mine owner and installed and maintained at his expense.

HAULAGE EQUIPMENT RECKONED ON COST-SHEET

Turning now to the mine, it is clear that the mine-haulage system consists of the entire equipment, including motors, cars, rails, track material, transmission lines, switches, etc. This haulage equipment is inventoried and valued at a specific sum. The expense of maintenance of such equipment, which includes a proportionate sinking fund, must be charged to the operating account as a monthly rental. By so doing, a new man coming to the mine will have no advantage over his predecessor in office, but will be subject to the same continuous charge and rental for the haulage equipment.

To complete the operating charges, in addition to the cost for power consumed and rental of equipment, must appear the wages of the motormen and helpers, the time for this service being charged according to the number of hours actually engaged in hauling. To these operating expenses must also be added costs for lubrication, repairs of motors and cars, which items would seem to belong particularly to the haulage account, while the upkeep of transmission lines and tracks belongs more properly to the equipment for which the haulage account is charged a monthly rental. My claim is that the charge for motor haulage, to be strictly fair, should be based upon the wages used and the material and current consumed. The last named item should be measured by a meter at the mine entrance.

Jeddo, Penn. J. KENVIN.

Freezing of Shafts in Winter

Letter No. 4—As zero weather approaches, managers of shaft mines are naturally concerned over the problem of keeping the shaft clear of ice in the colder months to come. The freezing of a shaft presents a trying proposition, and one that can only be successfully solved after a series of experiments to determine the effectiveness of seemingly practicable schemes.

In exceptionally cold winters, it has happened that an air shaft has been closed completely by the accumulation of ice; and where the hoisting shaft is the intake or downcast the mine has been forced, at times, to temporarily suspend operations, from the same cause. Before suggesting a remedy for this condition, allow me to cite one or two instances in my own experience.

AN INSTANCE OF A FROZEN HOISTING SHAFT

The first instance occurred in a 300-ft. shaft, where the hoisting compartments were the main intake for the mine. The shaft was timbered with wood and the seepage of water was excessive. A few days of freezing weather would make it necessary to employ a force of men working in relays to remove the ice sufficiently to permit the cages to pass. Two, and sometimes four men, were on the cage at once cutting ice, the cage being hoisted 2 or 3 ft. at a time. Much of the ice cut fell to the bottom of the shaft and had to be cleared from the sump and hauled away into some abandoned portions of the mine.

In severe weather, the cage would freeze fast to the guides in a few minutes; and it would be necessary for the engineer to use slack rope to jerk it loose. I recall one instance where it was necessary to hoist the men out of the shaft with a rope when it was impossible to free the cage.

One can understand the danger of these undertakings when it is explained that the hoisting engine was a duplex 18 x 32 in., operating under 100 lb. gage pressure, the hoisting drum being 7 ft. in diameter. The cages were of the self-dumping type and weighed between 4 and 5 tons, while the hoisting rope was 1⅛ in. in diameter. Many times, a full drum (22 ft.) of slack rope and a full head of steam was used to get the cage loose from where it was frozen in the shaft.

When running the cages at night, during freezing weather, the usual practice was to hit one bottom and one gooseneck and catch the cages on the rebound with a full head of steam. One can imagine the enormous strain thrown on the hoisting machinery, cables, head-

frames, sheavewheels and cages, under such conditions; but these crude methods were the only ones known at that time. I have cited these instances to show the seriousness of the situation, and will now explain the simple manner in which these conditions were changed.

In the left hoisting compartment, an uncovered 2½-in. steam line supplied the steam to operate two pumps. As a result, there was but half the trouble from ice on that side of the shaft, the principal trouble being experienced in the right compartment where there was no steam pipe.

Freezing Prevented by Small Steam Line

By the plan now adopted, a ½-in. pipe was tapped into the steam supply line at the top of the shaft, and from this a ⅜-in. line was run 50 ft. down the left compartment, and two ⅜-in. lines were extended down the right compartment for the same distance. These were put in diagonally opposite corners of the shaft. A ½-in. valve controlled the flow of steam in these three pipe lines, under a pressure of about 90 lb. per sq.in. When hoisting coal, only a small amount of steam was admitted to the shaft, owing to the dense fog created.

A little difficulty was yet experienced by the formation of ice on the extreme right guide. This was overcome, however, by securing a can on the top of the cage and connecting two ¼-in. pipes in such a manner as to conduct the strong brine solution in the can and distribute it equally over the guide.

In January, 1918, the thermometer registered from 10 to 24 deg. below zero nearly the entire month. During that time the services of two men were required at night. The worked from two to four ours each night, clearing the cage seats and bottom landing so that hoisting operations would not be hampered the next morning. There is, now, practically no trouble with ice at this mine.

Another instance that I will mention occurred at the mine where the air shaft was the downcast. On several occasions, this shaft froze nearly solid at the bottom. The usual procedure, at such times, was to work men in relays and pay them double time for cutting and hauling the ice away from the bottom of the shaft. Owing to the exposure to the severe cold, men refused to work at any price until milder weather set in. It was, then, a case of shutting down the mine, which generated a great deal of gas. It is needless to say that these conditions entailed a large expense item.

In this second instance, the difficulty was overcome completely by connecting a ½-in. steam line to the steam supply for the fan engine. This was run down the shaft about 50 or 60 ft. No shutdowns have occurred by reason of the formation of ice in the shaft since; and, to the best of my knowledge, not a single man has worked on the shaft bottom for the purpose of clearing it of ice.

Amsterdam, Ohio.

Waste of Coal

Letter No. 1—When reading the short article regarding the alleged waste of 150,000,000 tons of coal in the United States, each year, as published in *Coal Age*, Nov. 28, p. 973, I was deeply impressed with the illustration, showing this amount of coal as a solid cube 1785 ft. on a side. It seemed to me that I must be dreaming and I pinched myself to make sure that I was awake and had all my senses.

It was my desire, at once, to flatten out this cube so as to represent a 6-ft. seam of coal, and I started to calculate the number of acres it would cover. The article states that the cubic contents of 150,000 tons of coal is, practically, 5,700,000,000 cu.ft. There are 43,560 sq.ft. in an acre, and the cubic contents of a 6-ft. seam covering 1 acre would be, therefore, $6 \times 43.560 = 261{,}360$ cu.ft. From these asumed data, 150,000,000 tons of coal, in a 6-ft. seam, would cover $5{,}700{,}000{,}000 \div 261{,}360 = 21{,}809$ acres.

Let me assume, now, 10 mines, each hoisting 2000 tons of coal per day and working 300 days in a year. On that basis, the time required for these 10 mines to work out such a tract would be $150{,}000{,}000 \div (10 \times 300 \times 2000) = 25$ years.

Waste Estimated in Labor Required to Mine

Again, let us estimate the number of men that would be required to mine out this coal in 25 years, each man working 300 days in a year and mining an average of 10 tons of coal a day. The number of men required, in that case, would be $150{,}000{,}000 \div (25 \times 300 \times 10) = 2000$ men.

Further, if these men were paid 61c. per ton for loading this coal, the wages paid for loading alone would be $150{,}000{,}000 \times 0.61 = \$91{,}500{,}000$. Or estimating the coal burned by a single family, in a year, as 15 tons, the amount of coal represented by this waste would be sufficient to warm 10,000,000 families. The average consumption of coal in a year, by a single family, however, is considerably less than this estimate.

These figures impress us with the importance of conserving the fuel supply. The question comes home to us, How is this tremendous waste to be eliminated in the mining of coal. Let this proposition be discussed from a practical standpoint.

Russell Exline.

Sullivan, Ind.

Perplexities of Mine Foremen

Letter No. 5—I have been particularly interested in reading the letter of "Mine Foreman," *Coal Age*, Oct. 24, p. 793, in which he describes a difficulty that arose by reason of a coal cutter leaving 4 or 5 in. of bottom coal, in cutting a man's place. The coal cutter explained that it was necessary to raise his machine so as to avoid a roll in the floor.

Being well acquainted with the miner who worked in that place, I am informed that the machinerunner left 9 in. of bottom coal, which is a considerable proportion in a seam 3 ft. 9 in. in thickness. However, from my knowledge of the circumstances, I have no hesitancy in saying that the trouble could have been adjusted in a few minutes if the foreman had used his head.

The fact that the superintendent adjusted the matter without any trouble, later, shows that I am warranted in making this statement. In the conference that the superintendent had with the miner, I am told by one who overheard the conversation that the superintendent admitted that the miner was right. It will be remembered, also, that the Miners' Committee came to the same conclusion.

It is quite true that a mine foreman is frequently troubled and perplexed by small matters that are brought to him when they should be passed over quietly by the miner. It may also be true that the miner, in this case, went a little further than he was justified. Some would say that he should have fixed his place up himself and then demanded pay for his trouble. However, miners cannot be blamed for wanting to get their share and profit by the increased demand for coal and the general boom in the coal industry, today.

One does not have to look back many years to observe the great change that has taken place in mining conditions. Formerly, the miner was confronted with bad air, water in his place that he must bail out before he can go to work, while the scarcity of cars, timber and other supplies caused him much delay and loss of time. Notwithstanding the present improved conditions, it often happens that miners expect too much, and the mine foreman's patience is sorely taxed. On the other hand, we find many foremen who feel themselves above the miner and use their authority to deny what is the miner's just rights.

Advice to Mine Foremen

Let me urge, here, that every foreman should be careful and know he is right before taking a stand against his men. Even then, it is not well for a foreman to "flatly refuse" a miner's request. Not long ago, I heard Mine Inspector Elias Phillips advise a mine foreman, who had stood out against a request of his miners and was, himself, in the wrong, about as follows: "There is one advice I want to give you. Be sure you are right before you take a stand against your men. If they are right and you are wrong, you might as well quit; but if you are right, they will soon find it out and you have gained a point."

While it is difficult to deal with some men, good judgment and careful study of human nature will go far to lessen the perplexities of mine foremen. A machinerunner, in attempting to avoid a roll, may leave more bottom coal than is necessary, but the foreman should be able to see when this is the case and allow the miner what is right. It is poor policy on the part of a foreman to allow such a matter to go before the Miners' Committee and even then refuse to abide by their judgment. He had better fix it up quietly with the man and do what is right if it is possible to satisfy him, in reason. MINER.

Homer City, Penn.

The Miner and Safety

Letter No. 3—It is with the deepest interest that I read the letter signed M. H. G., *Coal Age*, Oct. 10, p. 707. I feel justified in stating that there is no more important work with which mine officials are charged than looking after the safety of their men. At the present time particularly, it is the official's duty in any industry to use every possible means of conserving the man power, which is so important an item to the nation, in its need of increased production.

In my opinion, the fact seems to be well established that most of the accidents that happen to miners could be avoided with a little foresight and by taking proper precautions. The same is not true of other classes of labor in the mine where men fall victims to accidents wholly beyond their power to avert.

It is my belief that safety should be taught universally, not only in coal mining but in every industry throughout the country. It would seem that there is no better way to show the need of workers taking the necessary precautions for their own safety than to illustrate, by pictures, how accidents happen and how they may be prevented. A campaign in the interest of safety, similar to the recent meeting of the National Safety Council at St. Louis, cannot fail to have a noticeable effect in reducing the number of accidents in mines, and causing men to heed the warning of "safety first."

Money spent in conducting such campaigns will always prove a good investment to any community. The large amounts now paid in compensation for fatalities would realize a greater gain if used to conduct a much needed safety campaign. It would pay for all the posters and advertisements necessary to impress lessons of safety in a way that would reduce avoidable accidents.

Permit me to say that there is nothing more effective in keeping a man from taking unnecessary chances while at his work than to have thoughts of his family who are depending upon him for support brought before him by such sympathetic pictures as were used to illustrate the letter of M. H. G. to which I referred previously. The leavetaking of the wife and baby in the morning, as shown in the first picture, when the miner is cautioned to be careful for the baby's sake, is a sad contrast to the scene described in the third and last picture, where the lifeless body of the uncautious miner is being brought to his desolated home. What more could be asked to induce miners to take these necessary precautions, not only for their own safety, but for the welfare of others dependent on them? Pictures impress themselves on the brain and cannot be effaced, while words of caution are quickly forgotten.

Foremen Must See Their Orders Are Obeyed

As stated in the letter of Lewis R. Thomas, Nov. 7, p. 877, it is the experienced miner who is the most frequent victim of serious accident. He is the one who is the most prone to take chances, depending on his long experience and freedom from harm. But, exemption from injury in the past is no guarantee of a like experience in the future.

For a foreman to order a miner to take down a bad piece of roof, or set a needed post for his protection, is not enough; but he should see that the work is done at once. Where a place is found to be dangerous and the miner is instructed to make it safe before proceeding to work, the driver should be told to set no cars in the place until the work is done. In the morning, drivers should be given a list of places that are dangerous, and forbidden to set cars there until further orders.

To show the need of taking every precaution, let me recite briefly a serious accident that happened to a car runner who was not informed as to what places were dangerous. The fireboss had marked a dangerous place in the morning, and fenced off the entrance on the haulage road so as to prevent anyone from going into the place unwarned; but did not consider it necessary or think of placing a similar warning at the crosscut leading from the adjoining room. It was through this lat-

ter opening that the driver entered the place just in time to be caught by the falling slate. It was his good fortune at the time, however, to be standing at the side of a car, which broke the fall of the slate and saved his life. In this position he was found a little later and rescued.

The incident just cited shows how a fireboss will seemingly comply with the requirements of the law and, yet, an accident may follow. In this instance, the car runner was accustomed to travel through the crosscuts from room to room, and had he been given a list of those rooms that were dangerous, he would have been warned and the accident might not have happened.

Inspect the Timbering of All Working Places

Mr. Thomas suggests, at the close of his letter, the careful inspection of miners' places to see that they comply with regulations in regard to setting posts a specified distance apart along the face. Miners should not be permitted to exceed this distance. Another condition that is dangerous occurs in low seams where roof slate or rock must be taken down to make headroom for the car, so that it can be brought near enough to the face for loading. I see no reason why a miner should be permitted to mine under such rock for a distance of 10 or 15 ft., for the purpose of saving a little powder and extra work. In doing this he invites an accident.

In mines where it is necessary to lift bottom in order to get headroom for the cars, I have sometimes seen miners advance 30 ft. or more before doing the work of lifting the bottom. While advancing beneath such rock, only temporary timbers are set, and these are very liable to be discharged in blasting the coal. The permanent double timbers are only set after the bottom rock has been lifted. To prevent such a dangerous condition, the working places should be carefully watched by the foreman and his assistants.

In closing, I want to say again that safety should be taught universally and harder and more rigid rules made and enforced for the safety of the miner, who is too often prone to take his life in his hands and assume unwarranted chances. Safety, in coal mining, should not be treated as a cold business proposition, but should receive the hearty coöperation of every mine official and mine worker, whatever his position. All are alike responsible.

Joseph R. Thomas

Plymouth, Penn.

Letter No. 4—I was deeply interested in reading the letter of Lewis R. Thomas, *Coal Age*, Nov. 7, p. 877, and quite agree with him in all that he has stated concerning the attitude of the experienced miner when he is questioned regarding the condition of his working place. More miners are killed by falls of rock and coal who claimed to be more experienced than those who make no such claim. The reason for this is that the man who claims to be experienced in mining coal is very apt to be careless in regard to timbering his place, whether the roof is good or bad. It seems to be his desire to show his experience by his seeming disregard of danger.

In the State of Colorado, conditions in the mine vary so continually that there are hardly two mines having like conditions of roof. In one mine, the coal will be overlaid with a hard sandstone roof and, again, this will be replaced by a drawslate above the coal. In places, there is a slate roof with numerous slips running in all directions. In some of the mines, the roof is full of "pots," or "Mexican hats," as we call them.

Only the truly experienced miner knows how to cope with these varying conditions and protect himself from danger. In order to make the mining of coal safe, in these mines, the state mining law requires that such a method of timbering the roof and spragging the coal shall be adopted, in each mine, that shall securely hold the roof, sides and face and meet with the written approval of the chief inspector of coal mines.

Chief Mine Inspector James Dalrymple insists that where coal is mined by machinery, props shall be set not more than 6 ft. from the face nor more than 5 ft. apart, with cap-pieces not less than 12 in. long. He also requires that all drawslate between the face of the coal and the timbers shall be taken down where such slate exists above the coal.

Mr. Dalrymple claims that the present method of timbering, by setting posts at stated distances apart regardless of conditions in the roof, is far safer than the old method of timbering where the miner relied on the sounding of the roof. He claims that roof conditions change when there is no change in the sound, and the method of timbering adopted protects the miner against these changes in roof conditions.

Mine Officials Urged To "Get on the Job"

Not only is the fireboss, in Colorado, required to examine the roof in each working place, to see that it is safe for work, when making his morning rounds, but the mine foreman or his assistant must visit each working place every day and see that it is timbered as the law requires. The foreman or his assistant must see that this is done before he leaves the place. Instead of enlarging, further, on the many conditions that lead to accidents, let me urge that it is the duty of every mine official to get on the job and see that each miner complies with the mining law and the mine rules and regulations in force at each mine.

Everyone familiar with mining knows that a miner's chief aim, in going into a mine, is to load every ton of coal possible and it makes little difference whether the man is an experienced miner or not; his only thought is the almighty dollar. Therefore, as long as the miner is paid for every ton of coal he can load, it is useless to depend on his individual regard for safety. Someone else must look after that. While we boast of our years of experience in mining, it is a fact that many of us would not be alive today had it not been for our interest in the other fellow's safety rather than in our own.

I recall a sad accident that happened to a mine foreman who found two men working in a place that was unsafe. After ordering the men out of the place and sending them home, the foreman returned to examine the roof more closely and was caught by the fall, which occurred suddenly, and killed him. He saved the lives of two of his men; but, relying on his experience, risked his own life and lost it.

In closing, let me impress on the minds of all mining officials that the safety of the miner is in their hands. Compel strict compliance with the mining laws and regulations and satisfy yourself that every man is working in safety, which is your duty.

Farr, Colo. Robert A. Marshall.

INQUIRIES OF GENERAL INTEREST

Blow Struck by Steam Hammer

Will you kindly give, in the columns of *Coal Age*, a formula for calculating the blow struck by a steam hammer? SUBSCRIBER.

Upper Lehigh, Penn.

As was explained in *Coal Age* a short time ago (Vol. 13, p. 984), it is only possible to calculate the energy stored in a hammer at the moment the blow is struck. This energy is expressed in foot-pounds, being the product of two factors, namely, the force of the blow and the distance in which the hammer is brought to rest. It is clear, therefore that the force of the blow, in pounds, can only be ascertained when the distance is known through which the hammer is brought to rest and this distance will vary with the density of the material struck.

To illustrate, a block of lead or other soft pliable substance, under a steam hammer, will develop a much less force than would result when a block of iron or steel is struck the same blow. For example, assuming that a blow of an energy of 1000 ft.-lb., or 12,000 in.-lb., falls on a block of lead, compressing it, say $\frac{1}{4}$ in. The force of the blow is then $12{,}000 \div \frac{1}{4} = 48{,}000$ lb., or 2 tons.

Again, assume the same blow falls on a block of malleable iron, causing a compression of, say $\frac{1}{16}$ in. The force of the blow, in this case, is $12{,}000 \div \frac{1}{16} = 192{,}000$ lb., or 96 tons.

The question of the force of a blow struck by a hammer is of little practical value, being only relatively suggestive.

Steam Boilers at Coal Mines

Give briefly the more common causes of boiler explosions, and state the types of steam boilers in most general use at small coal mines.

———, Ky. SMALL OPERATOR.

The more common causes of boiler explosions, as they occur in coal-mining practice are the following: (1) Low water in the boiler and the consequent overheating of the boiler plates and tubes when in charge of an incompetent fireman. (2) Lack of proper inspection and cleaning of the boiler at regular intervals. (3) The use of impure feedwater, resulting in the undue incrustation of the interior surface of the boiler, necessitating forcing the boiler and burning and blistering the fire plates. (4) Improper setting of the boiler, or settlement of the foundations, thereby bringing undue and harmful strains on the joints and other parts which become weakened and give way without warning.

Except in large power plants, the type of boiler commonly found at coal mines is either that known as the flue boiler or the return-tubular boiler. The former is a cylindrical boiler 5 or 6 ft. in diameter and, perhaps, 30 ft. long, having two flues 10 or 12 in. in diameter and extending the length of the boiler. The boiler is heated by a furnace placed under the front end, the flame passing over a firewall to the rear and returning through the flues is conducted by the breeching to the stack.

The return-tubular boiler is of practically the same construction, except that it is generally shorter and the flues are replaced by a large number of small tubes 2 to 4 in. in diameter. More up-to-date power plants employ a type known as the water-tube boiler, which consists of a series of inclined tubes surmounted by a horizontal drum, with which the tubes are connected in a manner to permit of the free circulation of the water through the entire system. By means of baffle-plates the flame and hot gases of the furnace are made to circulate up and down among the tubes before reaching the stack. The chief advantage of water-tube boilers is that they are more highly efficient and less liable to explosion.

Frogs and Latches in Mines

Kindly explain what is meant by the number of the frog, in a mine switch; and how to find the number of any frog that is on hand. For example, the frog I have here measures 3 ft. long, from the point of frog to the end of the two rails, which have a spread of 8 in. in that distance. Also, please explain what should be the length of the latch, in a mine switch.

Steubenville, Ohio. DAYMAN.

These questions have been thoroughly answered in the reply to the inquiry on "Mine Switch Calculations," *Coal Age*, Nov. 21, p. 961. A frog having a spread of 8 in. in 3 ft., or 36 in., would be a $4\frac{1}{2}$ frog. The number is found by dividing the length of frog by the spread; thus, $36 \div 8 = 4\frac{1}{2}$, the number of the frog. It is more common, however, to measure the entire length of the frog, end to end, and divide this length by the sum of the spread, measured at each end, as explained and illustrated by the figure, on page 961.

As there explained, also, the length of a switch latch, in coal mining, will depend on the radius of the curvature of the switch rails, and the desired clearance between the latch and the main rail at the hinge or pivot on which the latch swings. The length of the latch is found by multiplying twice the radius of the curve by the desired clearance, both expressed in feet, and finding the square root of the product.

For example, using a $4\frac{1}{2}$ frog and a track gage of 3 ft., the length of lead rail is $l = 2gn = 2 \times 3 \times 4\frac{1}{2} = 27$ ft. The length of the radius of curvature is then $R = nl = 4\frac{1}{2} \times 27 = 121\frac{1}{2}$ ft. Then, assuming a clearance between the latch and the main rail at the hinge of, say 4 in., or $\frac{1}{3}$ ft., the length of latch is $x = \sqrt{2Rd} = \sqrt{2 \times 121\frac{1}{2} \times \frac{1}{3}} = 9$ ft.

EXAMINATION QUESTIONS

Miscellaneous Questions

(Answered by Request)

Ques.—A column pipe 100 ft. in height is full of water. A hole is bored in the pipe at the bottom and another hole halfway down. With what velocities will the water issue from these two holes?

Ans.—The jet of water that issues from the bottom hole has a velocity due to the height of the column pipe. In other words, the theoretical velocity of efflux is that due to a head of $h = 100$ ft., which gives

$$v = \sqrt{2gh} = \sqrt{2 \times 32.16 \times 100} = \sqrt{6432} = 80.2 \text{ ft. per sec.}$$

Some authorities give a coefficient of efflux as 0.97, which makes the actual velocity of efflux $0.97 \times 80.2 = 77.8$ ft. per sec.

The flow from the hole halfway up the pipe has a velocity due to a head of 50 ft., which makes the theoretical velocity of efflux

$$v = \sqrt{2gh} = \sqrt{2 \times 32.16 \times 50} = \sqrt{3216} = 56.7 \text{ ft. per sec.}$$

Using the same coefficient of efflux gives, for the actual velocity, $0.97 \times 56.7 =$ say 55 ft. per sec.

Ques.—Suppose that, in a gassy mine, the quantity of air is 175,000 cu.ft. per min., measured in the return, and it contains 4 per cent. of firedamp, when the barometer is 30 in. (a) What quantity of firedamp is given off in the mine? (b) What is the least decrease of the quantity of air that will render the return air explosive? (c) What increase of gas will render the return air explosive?

Ans.—The question evidently means to state that the return current contains 4 per cent. of *methane* or *marsh gas*, as the term "firedamp" relates to any inflammable or explosive mixture of this gas and air, which would make the question quite indefinite. (a) The quantity of methane contained in the return current, on this assumed basis, is $0.04 \times 175{,}000 = 7000$ cu.ft. per min., which is the quantity of the gas given off in this mine.

(b) The lower explosive limit of pure methane is reached when the proportion of air to gas is 1:13. In other words, the gas forms then 1/14 of the firedamp mixture. To reach this condition by increasing the quantity of air would make the entire volume of air and gas in circulation, in the return airway, $14 \times 7000 = 98{,}000$ cu.ft. per min. This would show a decrease in the quantity of air entering the mine of $175{,}000 - 98{,}000 = 77{,}000$ cu.ft. per min.

(c) To reach the same condition by an increase in the flow of gas into the mine would require a quantity of gas equal to 1/13 of the quantity of air now entering the mine. The quantity of air in circulation is $175{,}000 - 7000 = 168{,}000$ cu.ft. per min. Therefore, the quantity of gas required to be generated, in this case, is $168{,}000 \div 13 = 12{,}923$ cu.ft. per min. This would mean an increase, in the quantity of gas generated in the mine, of $12{,}923 - 7000 = 5923$ cu.ft. per min.

Ques.—At what point in the mine would you expect firedamp to be standing, and how does firedamp appear in a safety lamp?

Ans.—A firedamp mixture being lighter than air may be expected to accumulate in rise workings, or at the head of steep pitches where the circulation is not sufficient to sweep it away. Firedamp will also be found where it is generated in sufficient quantity, in dip workings, where the air passing is not able to keep the place clear of gas. In such a case, however, the gas does not accumulate in the place, but the quantity generated is greater than the air current can remove.

Assuming that "firedamp" is an inflammable or explosive mixture of marsh gas and air, its presence in the lamp will cause the lamp to fill with flame and, at times, the mixture will explode within the lamp. If the percentage of gas present is below the inflammable limit, the mixture is not properly termed *firedamp*, but merely a mixture of marsh gas and air. The appearance in the lamp will then be manifest by the formation of a flame cap, the height of which will vary with the percentage of gas present.

Ques.—Is there a disadvantage or loss in having the air travel at a high velocity, and why?

Ans.—A high velocity of the air current circulating in a mine is a disadvantage, for several reasons. Greater power is required to produce the circulation than where the air current is divided into two or more splits and the velocity decreased proportionately. A high velocity of an air current is a source of annoyance and danger. Men cannot work in a high velocity of the air passing the working face, with any degree of comfort, and there is danger of igniting the gas generated at the face by the flame of the lamp being blown through the gauze.

Ques.—Describe what, in your judgment, you consider the best method of conducting the air current to and along the faces of the working places.

Ans.—The main air current in a mine should be divided so as to ventilate each district with a separate split of air. The air should be conducted to the farthest point inby, before being deflected into the rooms on its return. By this arrangement, the greatest pressure is made effective at the inby end of the workings. The air current should be made to sweep the coal face in each working place.

Ques.—What will be the pressure per square inch at the bottom of a column pipe on a slope 450 ft. long and pitching 42 degrees?

Ans.—The vertical rise of this column pipe, laid on a pitch of 42 deg. is $450 \times \sin 42° = 450 \times 0.66913 = 301.11$ ft. Assuming that the pipe is full of water, the static pressure, at the bottom of the pipe, due to this head, or the pressure when the pump is not in operation is $p = 301.11 \times 0.434 = 130.68$ *lb. per sq.in.*

COAL AND COKE NEWS

Harrisburg, Penn.

The United Mine Workers of America have outlined the following proposed amendments to the Pennsylvania Workmen's Compensation law, which will be submitted to the Legislature by the mine workers' organization at the coming session in January, 1919.

1. The waiting period of fourteen days now provided in the act should be eliminated and compensation begin from the date of injury.

2. The injured employee should have the right to select his own physician.

3. Payment of compensation for the loss of members of the body, such as an eye, a hand, an arm, a foot, or a leg, should be doubled in amount and length of time of payment.

4. Compensation should be paid for the loss of fingers and toes.

5. Compensation should be paid for all disfigurement.

6. Where sons in families meet with fatal accidents, parents should be compensated without the necessity of proving dependency.

7. Compensation should be paid to invalid brothers and sisters, regardless of age.

8. Compensation should be paid to a widow or wife or until she remarried.

9. The basis of payments of compensation should be 70 per cent. instead of 50 per cent. of the weekly earnings.

During the 1917 session of the Legislature no important changes were made in the compensation law, as the Governor of the Commonwealth of Pennsylvania stated he would not agree to any changes for two years, so that the law would have a fair test. It is thought that during the 1919 session organized labor will make great efforts to have changes made, and it is very evident that much opposition will be made to the proposed changes. Another fight is contemplated on the proposed "Old Age Pension Bill."

Refusal of the Pennsylvania Railroad Co. to permit the loading of coal into cars from wagons is declared by the Public Service Commission, in deciding the case of McPhilomy & McPhilomy, trading as the Franklin Coal Mining Co., of Brisbin, Clearfield County, to have been unjust, unreasonable and discriminatory, and the company is ordered to pay damages amounting to $500. The Commission, however, finds that the claim of the company that the railroad by failure to deliver cars prevented opening of a new seam of coal is not well found, and that the failure of the railroad to construct a siding was cause for damages aggregating $18,000.

Uniontown, Penn.

Influenza is slowly giving way in the Connellsville coke region. Production for the week ended Dec. 7 is 600,581 tons as against 574,729 tons for the week ended Nov. 30. Fuel officials and operators generally see in the increase not only the waning of the influenza epidemic but the results of the transition of the coke region from a war to a peace basis. The coming of peace found production at its lowest point since the war, and the week following showed another drop of 50,000 tons caused principally by the relaxation of the workmen to celebrate the event. Since then production has risen slowly and it is believed that production throughout the winter will hover around a weekly average of 600,000 tons' coal.

With a rating of 10,584 cars, a total of 5092 cars were lost by reason of labor shortage. Car shortage itself was held responsible for 782 cars. The cars shipped from the region loaded were recorded as 9942.

Coke showed an encouraging increase of 15,866 tons for the week, but an increase of only 2053 tons was noted in the shipment of byproduct coal. The aggregate production of 660,581 tons was divided into 270,993 tons of coke and 194,091 tons of byproduct coal.

Charleston, W. Va.

The year is being wound up in West Virginia insofar as the coal industry of the state is concerned, by what may be termed a stagnant market and with producers waiting to see what the new year will bring forth. Unless it does bring at least a few months of coal weather, West Virginia operators do not look for anything but a dull winter. So far there has been absolutely no such weather as might have been expected at this time of the year, and this has had a detrimental effect on the industry, some mines partly suspending operations and others shutting down. Such cases, however, are the exception rather than the rule.

The railroads—large consumers of coal—are trying to force prices down and have the extremely warm weather as an aid. Some coal from the state is going to the South American trade. Production may be a little larger than usual before Christmas, in order to supply consumers over the holiday period, when the output will fall short of requirements because of the usual holiday absences of miners.

Production, generally speaking, showed an improvement during the second week of the month with miners returning from military service and with certain labor troubles adjusted. Various factors combined to restrict the output of the Fairmont region during the week ending Dec. 14, a shortage of cars being the chief impediment to normal production. Further trouble was experienced in getting prompt placement of cars, and while the health situation was gradually improving yet many mines are still short of their entire complement of men owing to cases of influenza.

As a result of lack of motive power, and contributing trouble, the Baltimore & Ohio was unable to furnish empties anywhere approaching ordinary requirements, as it has been able to do during November. Some encouragement was lent to the market situation by an influx of orders for shipment to South America. Railroads are still using rather large quantities of steam coal in the East.

Fairmont, W. Va.

Labor conditions and the discussion of possible legislation occupied the time of the Northern West Virginia Coal Operators' Association at a meeting held here on Saturday, Dec. 14, attended by more than 100 members from Clarksburg, Elkins, Philippi, Morgantown, Kingwood and many other points.

A report made by Secretary F. J. Patton disclosed that the membership had grown from 77 operating companies having 147 mines to 154 operating companies with 238 mines.

A report was submitted by Chairman A. C. Beeson, of the Four States Coal Co., for the transportation committee dealing with such matters as compensation for "deadwork," etc.

Improvements being made by the Baltimore & Ohio Ry. in an effort to better transportaion facilities and the general improvement in the car situation were related by S. D. Brady for the committee on transportation.

It was suggested that the coal companies should maintain the Department of Mines and that the inspection forces should be increased because of the large number of new mines established in the last year. Mr. Isner declared the legislative committee was of the opinion that in one respect the mining laws should be amended, since under the present statute if an operator does not drain his mine he may be prosecuted, and if he does drain it into a stream he runs the risk of being prosecuted for polluting the stream.

The afternoon session was largely devoted to a discussion of future prospects and present conditions of the industry. Various labor questions also received a share of attention.

Secretary F. J. Patton stated that the association had received definite promises that there would be no discrimination in the car supply and other forms of transportation service against the Fairmont district as there had been in the past. One of the features of the afternoon session was an address by A. W. Calloway, director of bituminous distribution for the United States Fuel Administration.

Birmingham, Ala.

Coal production in the Birmingham district during the week ending Dec. 7 shows an increase of nearly 60,000 tons over the figures for the week ending Nov. 30. The week the output was 381,065 tons against 322,591 tons for the last week in November. The output for the week ending Dec. 14, according to the majority of the operators' unofficial figures, will show an increase over these figures also.

The shipping of coal into North Georgia by Kentucky operators will not be affected appreciably by the removal of the zone system, as that district has been part of the Kentucky and Tennessee zone for some time. Every ton that can possibly be mined is badly needed by manufacturers throughout the districts supplied by Alabama mines. Miners and operators are being urged to hang up record production marks by Government officials and the larger consumers of fuel.

Reports are current to the effect that the Woodward Iron Co. will announce plans for expansion in the Bessemer district shortly, whereby sixty new Koppers byproduct coke ovens will be built by that corporation in the near future. There is also much speculation in the district as to other expansion of the company, and it would not be surprising, expert authorities say, to see that company branch out into the steel producing business.

At present there are four of the company's five furnaces in operation. The big byproduct oven plant at Woodward is undergoing considerable repair work. The company owns thousands of acres of coal lands, which are being steadily developed. A new mine, a short distance from Dolomite, is now ready to produce coal.

Contracts for coke are being offered practically every concern of this nature in the entire district, but few are being accepted, as the district is suffering from under-production of the product. Foreign countries, particularly Mexico, are clamoring for the fuel to be used in smelter work.

The announcement that Director General of Railroads McAdoo had approved the expenditure of $1,600,000 for additional equipment to be used in the operation of the Warrior River barge transportation system was hailed with joy throughout the Birmingham district.

Victoria, B. C.

Experiments have been at progress at the collieries of the Canadian Western Fuel Co., Nanaimo, B. C., for the last two months in the effort to arrive at a solution of the problem of rendering impossible (or reducing the possibility to a minimum) a repitition of such an accident as that of last September, when the rope used in the Protection Island shaft broke, causing considerable loss of life.

The ingenuity of Thomas Price, master mechanic for the company, has resulted in an arrangement which seems to come close to meeting requirements. He has devised, and demonstrated its practicability in actual operation, a working model of a four-rope hoisting system. George Wilkinson, chief inspector of mines, describes the arrangement as follows:

"There are four complete hoisting ropes, an overwind rope and an underwind rope on each compartment of the drum. Four pulley wheels are used, two of them being set some distance above the other two to avoid fouling of the ropes.

"The ropes on the two upper pulleys cross. A drum of the usual dimensions is used and having an overwind and underwind rope on each compartment, the one rope is being unwound while the other is being wound.

"As the under rope is being wound on the drum and the cage is hoisted an overwound rope is being unwound and descends with the cage in the opposite compartment. The

operation is the same on the other side of the drum. The whole operation is made feasible by simply crossing the two ropes that lead to the two upper pulleys."

Mr. Wilkinson asserts that this is one of the simplest and most practical arrangements he has seen in use on safety ropes. He points out that everything is under control of the engineer, the same hoisting speeds being used on all ropes. Any possibility of slipping is avoided because all ropes are fastened to the drum.

Preparations are being made by the Western Fuel Co. for the installation of this double-rope system at its new mine, the Wakesiah, near Nanaimo, B. C.

PENNSYLVANIA

Anthracite

Drifton—Gambling on the prospect for an open winter, the Lehigh Valley Coal Co. has cancelled orders, effective at once, for the suspension of the Woodside coal banks operations, and these will be continued indefinitely. The fuel was dumped out as unsalable 65 years ago. The coal will be prepared at Drifton No. 1 breaker.

Wilkes-Barre—The Lehigh Valley Co. has filed a blanket appeal with the Luzerne County courts against the assessments on its anthracite bearing tracts within the Hazleton city limits. There is a general move on foot to advance the valuation of coal lands and to force anthracite operators to pay more taxes in the communities where they dig their commodity. Hazleton's assessment of the coal lands is over $3,500,000.

Edwardsville—The steel framework of the new Woodward breaker of the Delaware, Lackawanna & Western R.R., coal department, has been completed and work on the roof and installation of machinery is under way. The structure will cost over $2,000,000 and is said to be the first all-steel breaker built. It is 200 ft. high and about 15,000 tons of steel will be required. The work is being done by the bridge and construction department of the coal department, which will complete its task early in 1920.

Eckley—Mrs. Eckley B. Coxe, whose benefactions to the families of the miners in the Coxe mining villages have won her the title of "the angel of the hard-coal fields," has come to the rescue of the influenza stricken population of Eckley, named after her late husband. More than 10 per cent. of the town is down with the plague, and there have been many deaths. Mrs. Coxe organized a corps of doctors and nurses and sent them to take charge of the situation and supplement the efforts of the welfare department of the Lehigh Valley Coal Co.

Bituminous

Dawson—T. Robb Deyarmon has sold the 140-acre farm known as the John A. Fisher estate in Westmoreland County, to Millers Brothers. The farm is underlaid with coal.

Pittsburgh—The Crucible Fuel Co. has acquired the mine of the Cornell Coal Co. This is a slope mine in the Freeport seam of coal in the Allegheny Valley in Allegheny County, on the Conemaugh division of the Pennsylvania Railroad.

Heilwood—Ten more houses have been completed for the Penn-Mary Coal Co. at Clement, where Nos. 11 and 12 mines were opened recently. The second floor of the store building here of the Heilwood Co. is being remodeled and equipped as a clubroom for the coal company employees. Among the amusements will be pool and billiard rooms and a reading room.

Brownsville—Fire early Thursday morning, Dec. 19, destroyed the motor house, stockroom and office of the Pike mine, which is owned by the Diamond Coal and Coke Co. The loss was placed at $30,000. It is said that the fire was of incendiary origin. Within the last four years the company lost four tipples, one barn and a large store at West Brownsville.

Waynesburg—J. H. Strawn, receiver of the Farmers' and Drovers' National Bank of Waynesburg, has sold to Thomas M. Ingram and Frances I. Baily, of Cumberland township, two tracts of coal in Franklin and Center townships, with a total acreage of 283. The same purchasers have bought the J. B. F. Rinehart tract of 47 acres. The total consideration is said to be $40,000.

WEST VIRGINIA

Page—The Loup Creek Colliery Co. at its plant here, in the New River field, has installed and has in operation a new 200-kw. rotary converter.

Beckley—Among recent improvements made at the plant of the Boone Smokeless Coal Co., in the Raleigh field, has been the construction of a new substation, which was put in operation on Dec. 17.

Sand—With the completion of a siding at its operation at this place, the Brady-Thacker Coal Co., of which D. A. McDevitt is general manager, expects to begin the shipment of coal by the first of the year.

Logan—Latest improvements to be made by the Main Island Creek Coal Co. at its Omar plant, in Logan County, include the installation of two 200-kw. rotary converters, under the direction of the West Virginia Engineering Co., of Charleston.

KENTUCKY

Madisonville—Two men were killed by a premature shot in the Robert Forsythe mine near Providence, Ky., on Dec. 19. The men failed to come out at night, and a search was made, the bodies being found at 1 o'clock in the morning. The men were shotfirers.

ILLINOIS

Edwardsville—The Donk Brothers' mine here was closed down last week on account of two boilers at the power plant giving way.

Plainview—A new coal development is being promoted in this vicinity by A. W. and A. M. Crawford, who have successfully promoted a number of operations in Macoupin County. Drills have been ordered in and it is announced that prospecting will begin at once. Options are held on many hundreds of acres of land.

Witt—The two mines at this place have closed down, throwing 800 to 1000 men out of work. Many of them are seeking work elsewhere. Some have gone to the Kortkamp mine and some to Taylor Springs. The closing of the Witt mines came suddenly and without explanation. Most of the miners had bought Liberty Bonds, which were only partly paid for.

Taylorville—The Taylorville mine has been put out of commission temporarily by the fall of a cage on which six tons of coal was being hoisted. The axle of the sheave wheel broke at the top of the tipple and the weight of the coal tore away the automatic safety catches. The cage fell 200 feet to the bottom. Nobody was hurt. The 475 miners in the mine had to climb 600 feet up the airshaft stairs.

Carlinville—Coal was reached last week in the new mine promoted by Carlinville men, and the first load was sold on the public square for the benefit of the Red Cross. The sinking of the shaft was necessitated by the sale of the Carlinville mine several months ago to the Standard Oil Co., followed by the announcement that the new owners would not supply the local trade. The shaft has been cemented as it was dug, and as soon as screening equipment arrives the mine will supply all the needs of the community. In the meantime mine-run is being sold.

Hillsboro—One of the largest transactions in coal lands in the history of the trade is about to take place at Farmerville in this, Montgomery County. The Elly coal lands, in the north and west part of the county, which were taken over by the custodian of alien property, are to be sold. The lands contain extensive deposits of coal, some of the veins being 10 to 14 ft. thick. The lands, comprising several hundred acres, were held by the Elly Coal Co., which was organized in Germany, where most if not all of the stock is held. The principal offices of the company are at Girard, Ill.

Foreign News

Sydney, N. S.—It is stated here that the Dominion Coal Co. has made a formal offer to Fuel Controller Magrath to lease or purchase the Florence mine of the Nova Scotia Steel and Coal Co. Under the offer, it is understood, the value of the property would be fixed by arbitrators, to be appointed by the Government. It is also announced that the Dominion Coal Co. will develop and operate its extensive submarine areas in the Florence district.

Paris, France—Soft coal is $20 a ton in Paris. A family of from one to five persons gets 132 lb. of coal a month for cooking if the family does not have gas, and 132 lb. for heating. Similarly, a family of six persons is allowed 198 lb. of coal for cooking and as much more for heating. In England coal is rationed in proportion to the number of rooms in the house. In France a family of two persons occupying a large house of 15 to 20 rooms gets no more coal than the family of two living in a two-room flat. Paris does not expect to shiver as it did last winter, as the municipal authorities will draw upon the 80,000 tons of dry wood that have been stored in warehouses for use in emergencies. Other French cities have similar wood stores.

Ottawa, Ont.—The Lignite Utilization Board, of which R. A. Ross, consulting engineer, of Montreal, is chairman, reports that the large plant which is to be established in Saskatchewan for briquetting the lignite coal of that province will not be in operation until the spring of 1920. Before proceding with the work of construction the board will devote six or eight months to preliminary researches with which object in view Edgar Stansfield and R. de L. French, mining and chemical engineers, have been commissioned to make a comprehensive inspection and study of the carbonizing and briqueting plants in operation in the United States, and are now engaged in that work. Six months more will be required for the construction of the plant and the installation of machinery, in addition to the time necessitated for commercial adjustments, so that the spring of 1920 is the earliest date at which the plant can be put in steady operation. The capacity will be 30,000 tons yearly, but this production is a comparatively small consideration as the chief object of its establishment is to demonstrate the commercial feasibility of the process and to induce private capital to engage in the briquetting of lignites, in order to replace the anthracite now imported into the Canadian West with the domestic product.

Personals

Samuel T. McMillen has resigned as superintendent the Fulton Run shaft of the Jefferson and Clearfield Coal and Iron Co. at Ernest, Penn.

Benjamin Bish has been made superintendent of the Loash Coal Co. mines at Knoxdale, Penn., to succeed W. B. McInch, who recently died of influenza.

Carel Robinson, of Russelton, Allegheny County, Pennsylvania, has resigned as general manager of the Superior Fuel Co., effective Dec. 31, to take charge of the mines of the Boone County Coal Corporation at Clothier, W. Va.

H. T. Booker has been appointed general superintendent of the United Coal Corporation, Pittsburgh, Penn., vice **Edward H. Coxe**, resigned. Mr. Booker's appointment takes effect as of Dec. 15. He will be in charge of the operation of the corporation's mines and all matters incident thereto.

Lieutenant Paul T. Norton, Jr., who resigned his position as division engineer of the Somerset division of the United Coal Corporation of Pittsburgh, Penn., about a year ago to enter the army, has returned from overseas aviation service. Lieutenant Norton expects to return to work, probably in his former position.

Charles M. Means, of Pittsburgh, Penn., head of the United States Fuel Administration division of bituminous coal inspection, has sent his resignation to Dr. Garfield, to take effect Jan. 1. Mr. Means, who is an engineer with offices in the Henry W. Oliver Building, began his duties in Washington on Apr. 12 last.

Captain John Gibson, Jr., of Pittsburgh, Penn., returned on Dec. 14 from Camp Humphreys, near Washington, D. C., where he has been in charge of training an engineer company for overseas service. Captain Gibson has received his discharge from the service and will at once resume his duties as general manager of the Penn Smokeless Coal Co. in the Union Bank Building, at Pittsburgh.

A. C. Callen, professor of mining engineering and head of the department of mining extension of the West Virginia University, Morgantown, W. Va., has been granted a four months' leave of absence, beginning Jan. 1, 1919, to make a survey and study of the various mining regions of the United States. **R. Z. Virgin**, who for some time has had charge of mine extension work, will take charge of Professor Callen's classes at the university during his absence.

Obituary

James Long, aged 76 years, of Hazle Brook, Penn., formerly superintendent of the Silver Brook, Black Ridge, Hazle Brook and Eckley collieries of the J. S. Wentz Coal Co., and a leading anthracite authority, died on Dec. 15 of pneumonia.

Trade Catalogs

Giant Semi-Diesel Fuel Oil Engine. Chicago Pneumatic Tool Co., Chicago and New York. Bulletin 34-W. Pp. 32, 6 x 9 in., illustrated. Gives the vital points in oil engine design and describes the details of construction, fuel requirements and general characteristics of the concern's fuel oil engine.

Green Materials Transfer and Storage Hopper. Green Engineering Co., East Chicago, Ind. Pp. 15, 8 x 10 in., illustrated. A booklet intended to show those who have materials to handle and to store the pictorial story of the Green hopper. Information is given concerning the erection of the hopper.

Economical Handling of Coal and Ashes and Reserve Coal Storage. Link-Belt Co., Philadelphia. Book No. 353. Pp. 52, 6 x 9 in., illustrated. Reprinted from a series of articles by Henry J. Edsall, M. E., which appeared in *Steam*, 1917-1918. Contains much valuable data, and is in effect a treatise on coal storing and coal-handling machinery.

Space and Speed in Steel Buildings. Milliken Brothers Manufacturing Co., New York, N. Y. Booklet, pp. 24, 6¼ x 9¼ in., illustrated. Describes the Standardized truss unit system of building construction, designed and manufactured by this company. Hundreds of buildings of this type have been erected for the Government in different parts of the country.

Jeffrey Standard Bucket Elevators. Jeffrey Manufacturing Co., Columbus, Ohio. Catalog No. 244. Pp. 71, 8½ x 11 in., illustrated. A well printed catalog, profusely illustrated, describing the advantages of using this company's elevators. Capacities of standardized elevators are given, and among other data that of how to select elevators and the general arrangement of the standard track hopper. Typical installations are shown, along with complete layouts and specifications.

Tool Steels. Carnegie Steel Co., Pittsburgh, Penn. Pp. 24; 5 x 7¾ in.: illustrated. Gives valuable data and tables appertaining to electric tool steels. The heat colors shown on page 12 and the temper colors on page 15 are really remarkable. The heat colors shown range from dark red to bright yellow, while the tempers range from normal steel to gray green. The different grades of steel produced by the Carnegie Company are listed and the uses to which each may be put.

Industrial News

Snoqualmie, Wash.—The Niblock coal mine is to be extensively developed by its Seattle owners.

Astoria, Ore.—The Port of Astoria Commission is giving serious consideration to the matter of the construction of a half a million dollar coal bunkers and dock in this city.

Gray's Landing, Penn.—The Consolidated Coke Co. is rebuilding its Donald washery at this place and has awarded Roberts & Schaefer Co., engineers, of Chicago, a contract for the reconstruction work.

Louisville, Ky.—After being out of commission due to fire for a period of nearly two years, the big plant of the Kentucky Public Elevator Co., grain handlers, will start operations within a few days. This concern operates a large steam plant and is located on the Illinois Central terminals.

Seattle, Wash.—The 23d annual winter mining session of the University of Washington, College of Mines, will begin Jan. 2, 1919, and last for three months. Full courses of studies will be given in quartz mining, coal mining and metallurgy, etc. The session is open without examination to all who are interested in mining.

Salt Lake City, Utah—Frank Waterhouse & Co., of Seattle, have closed a contract for large quantities of coal from the Peerless Coal Co., of this city. Waterhouse & Co. will act as distributors for Washington, Oregon, northern Idaho, California and the Hawaiian Islands. The Peerless Coal Co. is headed by James D. Murdoch and Ezra Thompson.

Columbus, Ohio—Federal Manager Connors of the Hocking Valley Railway Co., says that plans to spend $6,000,000 in double-tracking the road between Columbus and Toledo, and the making of other improvements during the coming two years, will go forward. One-half of the amount is to be expended in 1919 and the remainder in 1920.

Charleston, W. Va.—The damage suit of the Breamer Red Ash Coal Co. against the Sandy Ridge Coal and Coke Co. found its way to the Supreme Court, which a few days ago awarded a writ of error on the petition of the plaintiff company from the action of the Mercer Circuit Court in setting aside a jury verdict which gave the plaintiff damages.

Des Moines, Iowa—H. L. Stevens & Co., of Chicago, construction engineers, while excavating for a boiler room at the Brown Hotel, uncovered a good seam of coal. After 23 ft. of earth had been taken out the coal, which is said to be 4 to 5 ft. thick, was discovered by the excavators. The Brown Hotel is located at the edge of the business district of Des Moines.

Wilmington, N. C.—The Cement Products Co., manufacturers of the "Sanisep" portable sewerage disposal systems that have met with such large favor in many coal-mining communities, announces that effective Jan. 1, 1919, J. B. Shatzer will assume control of its sales department as sales manager. On the same date C. E. McKee, former sales manager, will cease to represent the company in any capacity.

Toledo, Ohio—The Kanawha & Michigan Railroad Co. pleaded guilty to nine counts in a twenty-count indictment charging rebating, in the Federal Court at this place. The company was charged with rebating to the Kellys Creek Colliery Co. The railroad company was fined $5000 and the coal company was fined $1000. The Tennessee & Ohio Central Railroad Co. pleaded guilty and was fined $1000 for failure to notify a consignee for 39 days of the arrival of a car of coal.

St. Louis, Mo.—The St.. Louis Fuel Committee has granted the request of the Breese-Trenton Coal Co. for a reclassification of the output of its mines at Breese and Beckemeier, changing it from Standard to Mt. Olive. The effect is to enable dealers to charge 25c. a ton more for the output of these mines than has heretofore been charged. A number of other Standard operators, in view of action in the Breese-Trenton case, are demanding the reclassification of their output.

Charleston, W. Va.—At the West Virginia Coal Association meeting here on Wednesday, Dec. 18, the executive committee formulated a plan to secure the weighing of coal near the eastern border of the state instead of at Tidewater, as is now the case, coal not being weighed until after it is dumped, causing serious delays in settlements. Realizing that a market will have to be found for excess production after peace is fully restored, the executive committee also gave serious attention to the future of the export trade.

Louisville, Ky.—A concern which will shortly be a considerable consumer of coal in the Louisville district is the Standard Oil Co. of Kentucky, which is erecting a million dollar refinery at Louisville, with rail and water connections via the Ohio River. This plant is designed on big lines, and is equipped to burn a tremendous amount of coal, having automatic stokers of the Illinois type throughout, both in the steam plant and for refining or distilling oils. The company's office is at Fourth and Bloom Sts., Louisville.

New York, N. Y.—The Byproduct Coke Producers' Association, which held a two-day session in this city last week, voted to divide its work into two groups—the Atlantic and Middle West. These groups will be presided over by a vice president of the parent organization and will hold separate meetings, but will meet as a national body frequently. The officers chosen were: President, W. H. Ball, of Syracuse; vice president for the Eastern group, Nils Anderson, of New York; vice president for the Middle West group, J. A. Galligan, of Chicago, and secretary, Parker H. Woods, of St. Louis. Mr. Anderson is the president of the Debevoise-Anderson Co., of 56 Liberty St., this city.

Charleston, W. Va.—There were fewer deaths in the mining industry of West Virginia through accident during November than has been the case for some time, the casualty list containing the names of 29 men, nine of whom were crushed under falling coal, etc., and 11 of whom met death on or under mining cars. Four men met death in connection with the operation of motors, this making a total of 25 deaths inside the mines, including a miner who was electrocuted. One man was killed in the machinery on a tipple and the other fell from a tipple. Two died from miscellaneous causes. The greatest number of deaths—seven—were in McDowell County, Logan being second with five and Wyoming with 4.

McAlester, Okla.—Spirited bidding and heavy purchases by the leading coal companies marked the sale of the segregated coal and asphalt deposits underlying the Choctaw and Chickasaw Indian Nations at McAlester on Dec. 11-14. Of coal and asphalt deposits, with an appraised valuation of nearly $14,000,000, more than $3,000,000 worth were sold outright. The Rock Island Coal and Mining Co., which furnishes much of the coal burned by the Rock Island Ry. lines, purchased these deposits to the value of more than $1,000,000. The Folsom-Morris Coal Co. also purchased deposits valued at about $1,000,000. Numerous smaller companies and individuals made purchases. The purchasers in most instances will begin at once to develop their properties.

Portland, Ore.—Shipments of coal from Alaska to Portland may become a real fact next year, providing sufficient tonnage can be obtained, according to the purport of a letter received by the Portland Chamber of Commerce from the Anchorage Chamber of Commerce. The coaling situation in the city is becoming a vital one in view of the increase of port affairs, and the recent organization of the West Coast Coal and Dock Co. is taken as an indication of activity of the coal question. This concern has been formed by Max Hauser, grain merchant, and several other prominent men of the city. It has leased the O. & C. dock on the east side of the Willamette River and it will immediately install the latest coal-handling equipment. The dock is capable of handling 50 cars at one time and will take vessels up to 650 ft. long. It is the intention of the company, which has been capitalized for $100,000, to handle Utah, Wyoming, Washington and foreign coal, and in addition to caring for the export and shipping needs it is planned to sell fuel to dealers at home. The wholesale trade only will be catered to.

San Francisco, Cal.—Plans and specifications have been completed by Beckman & Linden Engineering Corporation for the installation of a 20,000-kw. steam turbine generating plant on the Tesla coal mining property, recently purchased by that concern from the receiver of the California Safe Deposit and Trust Co. The steam plant is to burn powdered lignite from the Tesla mines and the power is to be sold commercially to assist in meeting the power shortage in the San Francisco bay district. Researches by Beckman & Linden indicate that one ton of powdered lignite will give the same efficiency as five barrels of fuel oil. With fuel oil at $1.67 a barrel and the powdered lignite selling at about $4 a ton, a saving of more than 50 per cent. in fuel costs is indicated. The investment for apparatus to burn the powdered lignite is not any greater than the investment required to install oil-burning equipment, Linden explains. Oil burners can be converted for this use at a low expense, he said. It is the intention of the company to market the lignite in powdered or unpowdered form, so that purchasers may powder it for their own use. Tests have been made here by the United States Fuel Administration which demonstrates the feasibility of using powdered lignite under a 50-hp. boiler.

New York, N. Y.—The demands of the marine workers of New York harbor will be submitted to arbitration, according to the decision of the National War Labor Board, of which former President Taft and Basil M. Manly are the joint chairmen. For the past few weeks it has been feared that the marine workers would stop work because of the refusal of the New York Boat Owners' Association, the Tow Boat Exchange and the Lighterage Association to accede certain demands, which included an increase in wages and an eight-hour day. The workers contended that the matter should be submitted to the Board of Arbitration, New York Harbor Wage Adjustment, for adjudication under an agreement signed several months ago. The boat owners held that the Board of Arbitration ceased to exist when the Railroad Administration withdrew from the arbitration agreement. Several times, pending the negotiations, the marine workers threatened to stop work, which would have resulted in tying up shipping in this harbor and in throwing about 60,000 men out of employment. The matter was finally taken up by the Washington authorities and on Saturday last a hearing of the grievances was held in the City Hall with the result that both parties were ordered to submit their claims to the Board of Arbitration for adjustment.

MARKET DEPARTMENT

Weekly Review

Coal Industry Hopeful for Future—Demand at End of Calendar Year Falls Off Considerably—No Tone to Coal Market—Anthracite Situation Improved—Bituminous Being Offered Freely—Low Grades Selling Below Government Maximum

WITH the close of the calendar year we find the coal industry turning hopefully toward the future. During the last twelvemonth the accomplishments of the anthracite and bituminous mines have been recorded with no uncertain hand. It has been a momentous year for coal. But what a contrast is presented between the fuel situation today and that which existed at the beginning of the year! Then the country was working at feverish haste. Plants occupied in the manufacture of war necessities knew no idle moment. The national smithy was engaged in the task of forging the links of a chain that was to bind militarism hard and fast. Uncle Sam kept calling for more and more coal as he worked the bellows. Today finds the task completed. Militarism has been shackled, never to free itself, we hope, and the embers under the national forge are no longer glowing with their former intensity. The need for coal is no longer urgent.

The present lull in the demand for fuel, however, is somewhat in the nature of a breathing spell. There is a great deal of uncertainty, a great deal of questioning. During the war the Government has had its controlling hand on practically every industry. This control is gradually being relinquished. During the war the Government was the largest purchaser of the output of our plants. Gradually the industries are being permitted to resume their normal relations with each other, and soon the coal industry will come into its own again.

At the immediate moment there is a decided lack of tone to the coal market. Anthracite demand is dull, owing to the unusually mild weather, and some shippers have received orders to discontinue the delivery of egg and pea sizes, as these coals are plentiful. The steam trade, too, continues to display evidences of inactivity. Many operators are unable to dispose of their tonnage of rice and barley, and some of the smaller shippers have been compelled to store their output of these sizes on the banks. The production of anthracite from Apr. 1 to Dec. 14 inclusive is estimated at 70,702,000 net tons, 1,474,000 net tons behind the output of the corresponding period of 1917.

With the exception of the high-volatile coals, there is sufficient bituminous to meet all demands. Some of the largest producers of high-grade coals report curtailed production on account of a recurrence of influenza, together with a short car supply. Illinois and Indiana mines are losing an average of one day a week due to no market. Ordinary grades of soft coal are being offered freely, and it is reported that quite a little tonnage is being sold below the Government maximum. At tidewater there continues to be a dearth of the good grades of bituminous for bunkering. The output of soft coal for the coal year to date is 431,242,000 net tons, an increase of 39,341,000 net tons over 1917.

WEEKLY COAL PRODUCTION

The improvement in production of bituminous coal reported during the week of Dec. 7 failed to continue during the week of Dec. 14, the estimate during that week placing production at 10,636,000 net tons, a decrease of 346,000 net tons, or 3.2 per cent. The production during the week of Dec. 14 for the first time since Oct. 26 exceeded the output of the corresponding week of 1917, such increase amounting to 1,443,000 net tons, or 15.6 per cent. Reports from the carriers show in central and western Pennsylvania, where the greatest demand for bituminous coal exists, that considerable improvement occurred during the week of Dec. 14 in car loading, while on the contrary in Illinois and Indiana, where approximately one day a week is lost by the mines due to lack of demand, the decrease in cars loaded was the greatest that occurred in any district during the week, amounting to 14 per cent and reaching the low level of the corresponding week of 1917.

For the coal year to date the production of bituminous coal is estimated at 431,242,000 net tons as compared with 391,901,000 net tons during the period Apr. 1 to Dec. 14, 1917, a gain of 39,341,000 net tons, or 10 per cent.

The production of anthracite during the week ended Dec. 14, estimated at 1,924,000 net tons, not only exceeded the week preceding by 117,000 net tons, or 6.4 per cent, but exceeded the corresponding week of 1917 by 146,000 net tons, or 8.2 per cent, and recorded the largest weekly production since Oct. 12. The daily average during the current week of 321,000 net tons was but slightly below the average for the coal year to date, and was 9000 net tons, or 3 per cent. below the daily average for the similar period of 1917. The total production for the coal year to date is estimated at 70,702,000 net tons, and falls below the production during the period Apr. 1 to Dec. 14, 1917, by 1,474,000 net tons, or 2 per cent.

Reports from the carriers show increased loading during the week of Dec. 14 in the central and western Pennsylvania districts and a considerable decrease from the central and southwest states. During the corresponding week of 1917 storms cut production to the low mark of slightly over 9,000,000 net tons, the loading during that week being considerably below that of the present week in all districts with the exception of the central and western states. The storm occurred mainly in Ohio, where the increase in weekly loading this year over last amounted to 9304 carloads or 72 per cent. All districts continue to report, for the coal year to date, an increase in cars loaded over the same period of 1917.

Bituminous coal to New England, during the week ended Dec. 14, is estimated at 326,497 net tons and is approximately the same tonnage as shipped during the week preceding. The rail tonnage during the week increased slightly, while the water shipments show a slight decline. The three northern harbors, New York, Philadelphia and Baltimore, report a falling off in tonnage loaded, while bituminous coal shipped from Hampton Roads increased approximately 18,000 net tons, or 15 per cent. While shipments during the last few weeks to New England were equal to not more than two-thirds of the weekly average for the coal year to date, total shipments for the coal year to date, amounting to 20,363,914 net tons, are in excess of the budget outlined by the United States Fuel Administration by 49,884 net tons.

Tidewater shipments of bituminous coal during the week of Dec. 14, while lower by approximately 23,000 net tons, or 3 per cent, than shipments during the week of Dec. 7, are holding up extremely well, and during the past few weeks have amounted to approximately 80 per cent of the weekly average for the coal year to date. The total shipments from the North Atlantic harbors and Hampton Roads for the coal year to date are estimated at 32,345,952 net tons, exceeding the requirements as originally outlined by the Fuel Administration by 2,780,976 net tons, or 9.4 per cent.

The production of beehive coke in the United States during the week ended Dec. 14 is estimated at 553,000 net tons, an increase of 10,000 net tons or approximately 2 per cent over the week preceding and a decrease of 21,000 net tons or approximately 4 per cent compared with the corresponding week of 1917. The daily average during the week of Dec. 14 is estimated at 92,000 net tons as against 96,000 net tons produced during the week of Dec. 14 of last year.

In the Connellsville, Greensburg and Latrobe districts of Pennsylvania production of beehive coke during the week of Dec. 14 amounted to 313,967 net tons. This production was brought about by the operation of the ovens at 70.2 per cent of full time as against 66.6 per cent during the week of Dec. 7, the improvement being attributed to better labor conditions. The same operators produced 180,900 net tons of coal during the current week as compared with 159,700 net tons of coal during the week of Dec. 7.

Byproduct coke production in the United States during the week ended Dec. 14, estimated at 578,871 net tons, while approximately the same as produced during the week preceding, exceeded the production of the corresponding week of 1917 by 150,000 net tons, or approximately 35 per cent.

The operation of the mine plants during the current week for the country as a whole was reported by the operators as 88.8 per cent of capacity. Out of a total loss of 11.2 per cent of full time, 5.5 per cent is attributed to repairs to plants, 2.1 per cent to lack of market and the balance to shortage of coal, labor troubles and other causes. Losses of full time on account of no market continued to exist in Massachusetts and Pennsylvania, the operators in these two states reporting approximately the same losses as during the week of Dec. 7. During the week, the supply of byproduct coal brought about improvement in operating conditions in New York and better labor conditions brought about increased production in Maryland.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is still running about the same as for the corresponding week of 1917. Road sales for both immediate and future delivery were less than for the same week of last year. Customers were in the market in greater numbers. Retail business in holiday merchandise has been excellent. Collections continue good.

American Wool and Cotton Reporter—The increased estimate of the cotton crop was a surprise to many, but it was not considered of any particular importance in so far as prices are concerned. Very high prices for cotton undoubtedly will be noted eventually on the basis of supply and demand because even a single moderate American crop would not be large enough to solve the world's problem.

Dry Goods Economist—In textile circles the interest switched this week from cotton to wool. Two big auction sales were the attraction, one of woolen and worsted fabrics by a leading producer, the other of raw material. Bidding was spirited during the first three days. Prices were from 12 to 40 per cent. below those on the date the goods were opened for last fall, according to the desirability of the merchandise. In cotton circles there has been a softening of prices for print cloths to the extent of 3 per cent. No reductions have been made, however, in quotations for fine-yarn cotton fabrics.

Bradstreet's—Animation flowing from holiday buying sharply contrasts with the slow movements evidenced in wholesale lines, with the effects of cancellations, with downward revisions of some prices, and with uncertainty created either by the divergent views as to the future expressed by prominent personages or by concern over the fact that the government has large supplies of unused materials to market. Inventorying is under way, traveling salesmen are in for the holidays, small-lot filling orders conveyed by mail are the rule, and in cases where unexpectedly large stocks have been revealed, the policy is to clear decks. In fact the general attitude as to manufactured goods is to reduce prices in order to hasten readjustments and make a market.

The Iron Age—An open market for steel products has come in the past week, various forms of finished steel having sold at from $4 to $6 a ton below the Government maximum prices established for the fourth quarter of the year. Among pig-iron producers, those who have chafed under the fixing of pig-iron prices by steel makers now feel that as the demand for their product is relatively greater than that for finished steel they will be able to get the old prices. On the other hand, many foundries are well stocked with iron. But Southern furnaces have declined to take on 50,000 tons of basic iron for England, and Japan is inquiring for 20,000 tons. It is to be said that the reduced prices have brought out no large amount of new business. In the East a 6000-ton plate contract was put through at 3c., the new figure, though some producers quoted the Government price. Now that the market is open, the possibility of further reductions is distinctly a factor.

Atlantic Seaboard

BOSTON

Little change in situation. Almost no buying in any quarter. Railroads send empties west in better volume. Coal movement east still further reduced and some railroads still trying to buy. Rumors of low prices for inferior coal, but nothing significant as to prices on quality grades. Scattering inquiries, but not so easy to get prompt shipment. Still hard to dispose of coal at destination. Large surplus of coal at Hampton Roads. Only restricted market over New York piers. Problem to furnish cargoes for barges and steamers in the trade. Anthracite looks easier. Rail movement about the same, but marked improvement looked for. "Storrow coal" reduced more than 50 per cent. Stove and chestnut still scarce. Difficulties over allotments and figures being cleared up gradually.

Bituminous—There are no marked indications of change in the general situation. The same disparity in cost between rail and water coal is much in evidence, and it can be said flatly that at the end of the calendar year there is no buying interest whatever. And beyond that there is no near prospect of any. Consumers will not make purchases until they have used the mongrel assortments now on hand, and when there is again anything like an open market the trade is sure to meet with some very discriminating buying. Apparently there will be a lot of insistence upon quality and that will have a strong stabilizing influence as to price. Production now curtailed because of influenza and a disposition on the part of labor to take things easy is quite likely to be close-hauled for months to come, and there is small chance of coal being mined much faster than the market will absorb. This, together with the certainty that a lot of consumers ordinarily dependent upon water-borne coal will try to line up for shipments all-rail, will lead the trade to watch developments very closely the next few months. It will be interesting to see the situation unfold as the present heavy reserve stocks become gradually depleted.

Today there is a minimum of buying in every direction. The distribution inland of tidewater coal has dropped off nearly 75 per cent, and for Pocahontas and New River in cargo lots there is practically no sale whatever. Consignees having deliveries due on contract are suspending shipments because their stocks are so large and their consumption has decreased to such extent. This is true of a great number of plants. Cotton mills, for instance, are curtailing more and more rigidly as their goods pile up awaiting renewed buying. Other textiles and producers of many different staple lines are having the same experience.

One of the few recent developments is the demand for empty coal cars by railroads serving mines, particularly in the Pittsburgh region. Railroad executives here have been plied with urgent telegrams to return such empties promptly, and the fact that eastbound movement with coal has lately been so light makes such inquiry all the more pressing. A surplus of cars is reported as still the prevailing situation in central Pennsylvania, and certain of the railroads continue in arrears on their receipts of supply fuel. The Boston & Maine, for instance, is still making purchases at Government prices and has difficulty getting sufficient for current supply. The fact remains, however, that this road is among those with a heavy reserve; not as heavy as in some years, but sufficient for ordinary requirements.

All-rail movement through the five New England gateways continues to slump with the advancing season, although apparently this time the season has little to do with it. The average for six days, ending Dec. 18, was only slightly over 200 cars daily of commercial bituminous. The daily average for the first 16 days of December, railroad fuel included, was but 278 cars. Latterly, railroad fuel alone has averaged only 50 cars per day, as compared with the 150 cars that were the usual mark in September. This has a bearing on the efforts of certain of the roads to arrange for coal in the open market. Certain large groups of mines regularly furnishing these supplies have suffered severely from the influenza and other causes affecting labor.

Prices as low as $2.20 have been quoted for inferior grades from Pennsylvania, but on investigation such offers appear to be based largely on expectation. It is questionable practice to exploit such proposals, for even low prices would not induce any substantial buying at this time, and they only add to the confused state in which the market finds itself at this juncture. Were the lower quotations followed far enough it would be found they applied to coal already mined, of doubtful character, and in the hands of people looking for ready money. On the quality coals there has been nothing a cent lower than the Government figure. Shippers of these grades have ample business for their present output, and notwithstanding their New England consignees are not taking their quota there is ample outlet for the coal in other directions, at least for the present. No significant change is noted in this respect, and it is quite possible there will be no considerable tonnage available for this market all-rail until buyers here are again ready to take on supply. Today there are only scattering inquiries, and while for these coal is readily found and for reasonably prompt shipment, yet it is plain that no comprehensive orders could be taken care of on anything like the same basis.

On the other hand, this territory is so plugged with coal in most directions that coal arriving at destination, undisposed of, is extremely hard to get rid of. Fuel authorities have had several cases on their hands lately where car service and reforwarding charges have piled up to a large figure. In Connecticut recently it was even seriously urged that coal awaiting disposition should be sold by the railroad for the freight, but this, of course, was an extreme case. None the less it shows that some parts of New England are fairly glutted with coal.

At Hampton Roads the excess of coal over bottoms reporting to load is mounting daily. The tonnage dumped for commercial purposes is as constantly decreasing, and were it not for Government requisitions and bunker trade, together with export tonnage, there would be actual congestion at the piers with a record low movement of empties back to the fields. Agencies in this market are imploring their principals to send the coal west or along the line, anywhere but for New England disposition, and the few loadings coastwise show the extent to which these prayers have been answered. Water-borne coal on the basis of the current marine freights is extremely hard to sell.

Shippers generally are getting alive to the very large tonnage of barges and steamers available for the coastwise trade the coming year. The figures give some reason for alarm, for there seems small prospect now of placing all that tonnage from tidewater ports until buyers shall have had a season-long try to get their supplies all-rail. This will mean a slow-starting year, with all the buying interest most reluctant to tie itself to water-borne coal. There have been intimations that the Shipping Board would reduce coastwise freights, but apparently no move has yet been made nor will be made until it is demonstrated either that the colliers now in use are not suitable for other trades or there is less inquiry for steam tonnage in other directions. As it is, the Hampton Roads shippers, in particular, have reason for being disturbed over the outlook.

Anthracite—The fact that Government requisitions are gradually being reduced, that the Anthracite Committee is not making so many demands on behalf of alleged suffering communities, and the further fact that shipments all-rail the past week have taken a slight spurt, have all caused the trade to realize that anthracite conditions are really much easier. The continued mild weather has its great effect on current consumption, and many cases there are where the householder will not need that "last third" about which there was so much worry just a few short months ago. An increasing number of retailers in widely separated parts of New England have been reporting comfortable stocks for the present, and there have even been whispers of cancellations on the part of those who were most vehement in their denunciation of "independents" who were refusing to ship a few weeks ago. These shippers will of course feel the effect first of easier conditions and in this market, if the truth were known, there will not be many hands turned to help them when they have their surplus sizes to market during the coming months.

Rail receipts show a slight improvement. Through the five gateways the average movement of domestic sizes for the first 16 days of December was about the same as for the first week, although recent days have shown quite an improvement. It is likely that in another week the movement will reach 400 cars daily.

Instead of 100 cars per day the New England Fuel Administrator is now having shipped to his order but 46 cars, and it is understood this will shortly be further reduced, if not wiped out altogether. The opinion in the trade is very strong against further emergency shipments, for the effect they have on efforts in regular channels to move sizes in proportion as they are produced. The fuel authorities should never have been allowed to consult the fastidious preferences of certain retailers quick to raise the cry of "famine" when their stove coal is depleted.

Sundry difficulties over allotments and tonnage figures are gradually being straightened out, in most cases, however, because it is realized that regulation will be short-lived and shippers are more and more taking situations into their own hands. In some cases to wait for fuel authorities to act would mean serious inconvenience to communities where there are large populations.

NEW YORK

Anthracite situation looks brighter, but shortage of the domestic coals continues. Demand for egg, stove and chestnut is strong, and consumers refuse to accept substitutes. Plenty of the smaller coals are available. Retail deliveries are almost at standstill. High-grade bituminous hard to buy at the mines and the demand at tidewater is slow. Cheap grades plentiful. Bunker demand heavy.

Anthracite—Conditions in this market have a brighter appearance. Reports indicate that more coal is coming here, but it does not include the sizes mostly in demand for household consumption. Weather

conditions have been in vast contrast to what they were a year ago, when those with good memories can recall that New York was in the grip of the bitterest winter it had ever had and the coal supply was down to rock bottom.

How much benefit New York City will receive now from the increased production reported from the coal fields remains to be seen. It has been learned that orders have been issued to producers and distributors that more than 350,000 tons of anthracite is to be sent to this tidewater during December and January for shipment to New England points. With this tonnage available it is believed New England will be provided for during the winter. Meantime New York dealers who are now, and have been, short of the needed domestic sizes for some weeks will have to continue to assure their customers that there will be plenty of coal available later on.

Producers report an improvement in conditions throughout the coal fields. Operations have been interrupted by new outbreaks of influenza, but the authorities believe it has about run its course. With the return to the mines of those who have been discharged from camps and from various of the war industries, operators expect the output this month will be close to normal. They point out that even with the lack of labor the output for eight months of the 1918-19 coal year shows a decrease of but 1,139,712 tons as compared with the corresponding period of last year.

Dumpings at the local docks for the week ended Dec. 20 were 6381 cars as compared with 6098 cars the previous week.

Shippers are not able to take care of their customer's wants for egg, stove and chestnut coals. There is a good supply of broken, pea and No. 1 buckwheat. Rice and barley are free enough to cause salesmen, who have but recently started to visit dealers for the first time in nearly two years, some worry.

Retail yards are piled high with these two small sizes, but the dealers would be willing to increase these piles if they could be assured of a supply of the larger coals either now or in the near future. This promise the salesmen cannot make, and as a consequence rice and barley continue to be troublesome, although many houses are reported to be making concessions.

Retail dealers' business is practically at a standstill. Consumers who in most cases have been fortunate enough to secure two-thirds of their winter's supply are refusing the remaining one-third, rather than accept substitutes. As a result deliveries are slow and no improvement is expected until much of the coal now in the consumers' bins has been used.

The dealers have been presented with demands for increased wages by the drivers and engineers employed by them, but as yet no reply has been made by the employers. The dealers contend that if the increases are allowed it will mean that the price of coal will have to be advanced to the consumer.

Bituminous—The market is confusing. High-grade coals are practically unpurchasable at the mines and stray cargoes available here are almost unsalable. There is no demand. Consumers either have their bins filled or are existing on their reserve stocks until such time as they are forced to go into the market. In most cases they look for a break in prices as soon as the Government relinquishes its supervision.

The situation in the mining fields can be summed up in the words of an operator who has just returned from a visit to his properties, and who said he had found there was no demand for coal, production was held back, by the "flu," and there were petty labor troubles. Others who have been in the coal fields report considerable uneasiness among the workers, who they say cannot get over the jealousy existing between them and their fellow union members in the hard coal fields, and who continue to believe they were discriminated against in the recent wage readjustment. Fear is expressed that this jealousy may yet lead to serious trouble and possibly strikes.

Local dumpings during the week ended Dec. 20 show that 6413 cars were handled at the tidewater docks as compared with 5250 cars the previous week.

Supplies of the cheaper grades of bituminous are plentiful, but not sufficient to cause a general shaving of prices, although it is reported some slight concessions have been made. As a rule buyers are not willing to take any of these grades unless they are compelled to do so to tide them over a possible shortage of the high-grade coals.

The final shipment of the so-called "Storrow" coal for New England was made this week, and it is expected that the accounts will be closed within the next week or ten days.

Bunker demand continues to be strong with plenty of ships to take all available coals.

PHILADELPHIA

Anthracite retail trade dull. Holding of egg and pea orders grows. Companies making better shipments of stove and nut. Consumers excess orders cause trouble. Dealers feeling better over situation. Suburbs in greatest need for fuel. Anxiety as to stocks on hand in spring. Flat retail price talked of. Bituminous trade lacks tone. Best coals scarce, but ordinary plentiful. Some price shading.

Anthracite—The retail business in this city is undeniably dull. There can be no doubt about it, and if coal were free there are many dealers who would be compelled to suspend shipments. As it is shippers report they are receiving numerous requests to hold up on egg and pea sizes.

Some of the smaller dealers are becoming anxious as to what they will do with their product, especially at their present prices, in the near future. It is not at all general as yet, but we hear of individual coal being offered to dealers far in excess of the amount purchased during the basic year of 1916-17, and in some cases where no coal is actually due them from the house offering it.

Local business in normal years is always poor around the holidays, and the unusually mild weather to date has had its effect; but no one looked for the slump this winter under any conditions. One representative retailer attributes the lack of eagerness on the part of the public to buy to the disappearance of all coal news from the front pages of the daily papers. While the papers were carrying "scareheads" everybody seemed to want coal, whether they needed it or not, but for the past few weeks, where the dealers know their customers have coal in their cellars they are afraid to deliver more, notwithstanding they hold unfilled orders. They fear it will be returned, and experience is teaching them to first notify the customer of the intended delivery.

One dealer reports having sent out sixty-five tons in one day, thirty of which were not accepted by the original consignee. The dealers are now becoming aware that the orders placed in the spring called for more coal than will be required by the householders. This means added expense to the dealers, for when the orders were filed with the fuel administrator they attached hundreds of stamps at 2c. per ton on these excess requirements, all of which is a total loss to the retailers. Efforts to collect this cost from the consumer almost invariably meets with disdain, so much so that few dealers are willing to ask for reimbursement.

It is now thought by some that the larger operators consented to increased allotments to various dealers as requested by the fuel authorities because they were all along satisfied that the whole situation was exaggerated. A number of dealers have admitted to us that they do not expect to sell before spring all the coal apportioned to them, and for which they made unusual efforts to get into stock in case of necessity, and should there be a still further increase in shipments to any great extent, some dealers will actually be compelled to hold their orders, especially in the absence of seasonal weather conditions.

Despite the fact that the consumers are pressing the dealers hard for stove and nut, the retailers themselves have lost much of the anxiety for coal that they possessed a few weeks since. Most of them now are fearful that they will be caught with a yard full of coal when spring comes, especially those handling the higher-priced individual coal, and with it the usual reduction in wholesale prices.

While egg and pea are rather plentiful there are many dealers short of stove and nut. Strange to say, the greatest scarcity appears to be in the suburbs, which is just the section of the city that it was proposed by the fuel authorities to care for early in the season. Mr. Lewis realizes the conditions under which coal is delivered in the outlying localities in bad weather, and he did all in his power to care for them first. No one will say why his wishes in the matter have not been fulfilled.

This week an advertisement appeared in the daily papers explaining the 75c. differential and why the dealers prices are at variance. The advertisement bears the signature of the fuel administrator, but like others this season the space was contributed by the Philadelphia Coal Exchange and was inserted to "square" with the public the retailer who buys individual coal and is compelled to charge higher rates than those who handle either company coal exclusively or both company and individual.

At a meeting of the West Philadelphia dealers this week a movement was started that is causing much interest and is now being considered by the retail trade in other sections of the city. It is proposed to make a flat retail price for all dealers. The idea seems to be to have the dealers who buy the cheaper coal raise their rates and the buyers of the higher priced coal lower theirs. Then in some way the dealers who advance their prices are to pool their excess profits in favor of those who reduce. Little has been said about the scheme, and while it is known that some dealers are unusually enthusiastic over the proposition the details are not yet obtainable.

The steam trade continues without any particular activity. It is true that all the heavy tonnage of buckwheat is being taken by the consumers, with the size at times becoming a little draggy, as we have heard of stray instances where individual shippers have offered an occasional car or so for domestic use. There continues to be plenty of rice and barley in the market and the big companies are unable to place all of their production, and some of the smaller shippers are compelled to store on the banks in the region.

The prices per gross ton c.o.d. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—There is a lack of tone to the soft-coal trade. Outside of the high-volatile coals there is sufficient coal coming in to meet the needs of the market. Some of the larger producers of high-grade coals report curtailed production on account of a recurrence of influenza, together with short car supply. There is plenty of ordinary coal being offered, and we have reason to believe that quite a little tonnage is being sold below the fixed price. We know a specific instance where a cut of 50c. was offered. The softness of the market is shown by the number of letters being received by consumers from operators and brokers offering coal. At tide there also continues to be a dearth of the good grades for bunkering.

BALTIMORE

Supply of all but best soft coals on market liberal, and purchasing comparatively light. First inclination toward price cutting seems overcome. Hard-coal supply at last flows in in good shape. Small lot sale prices fixed.

Bituminous—As one after another the mines which formerly supplied this section are reëntering the open market to some extent, and as the Government holdings of soft coal are now almost entirely confined here to the best selected fuels, a selling condition more nearly approximating that before the war, with the exception of prices, is being established. The inflow of coal is now liberal, while the demand from business here is comparatively light. Most of the larger industries seem pretty well stocked, although some that were not on the preferential list in war time are now casting about to get better grade coals to mix with stocks they now have, or coals still running on contracts with mines that were accepted as emergency sources.

There is a feeling in the coal trade that there will be plenty of market for the more desirable coals, although more care in preparation will undoubtedly be forced on some operations that have been able to ship anything at all in the past and get the Government price. This feeling has apparently had a strong hand in stopping an early inclination to begin to shade the Government maximum. The past week, while supply was as liberal as the week previous, there was little talk of offerings for any coal really worth while below the Government figures. At tide here the Government was only holding on to Pool No. 9.

Anthracite—The hard-coal situation has become active for the dealers here through heavy arrivals during the past ten days. For the first time in months the equipment for delivery of the dealers was taxed. It was reported that some 900 cars of hard coal were received here in a week period. The best part of it is that a considerable part was of stove and nut sizes, which had been rare.

A number of dealers joined the class of a full delivery of the two-thirds program for their customers, and started on a new round-up on the remaining one-third for customers. The mild winter so far, and the incoming receipts, largely from one big concern that had been far back on proportionate shipping, has saved the situation here for hundreds of homes that had been without coal on Nov. 1.

The local fuel administration is gradually reducing forces and will probably pass in the main from active work some time in February. In the meantime it has just set

a price for small sales of bushel, peck and 16½-lb. bags, which had remained constant for more than a year despite the increases in both wholesale and retail prices of ton lots. The new prices make an increase of 5c. on pea and nut coal on bushel sales and proportionately on smaller lots. The bag prices are advanced 1c. a bag of 16½ pounds.

Lake Markets

PITTSBURGH

Market softened somewhat, but best grades remain at full prices. Production increased. No shortage of miners.

The Pittsburgh district coal market has softened somewhat, but not nearly as much as Ohio markets as a whole, and the softening is confined to steam coal and the less desirable grades at that. Gas coal is very scarce and is difficult to buy even at the full Government limit of $2.60 for ¾-inch. Some producers are offering contracts for gas coal at the Government limit for a year and would be indisposed to sell at the price merely for a period that would carry the consumer over the winter.

Pittsburgh district operators insist that quality considered the Government price has been low relative to prices fixed for other districts, and that Pittsburgh coal is therefore worth the full limit price. They point out also that the season has been unprecedentedly mild and the fact that no very serious weakness has developed in the market is conclusive proof that there will be a very strong market the moment real winter weather develops.

The weekly production has crossed the million mark again, and last week probably amounted to fully 1,100,000 tons, against 1,065,000 tons produced the week before. A curious report that western Pennsylvania is experiencing a shortage of miners to the extent of 10,000 is flatly denied. Distribution of byproduct coal is now quite satisfactory, and the production manager has had practically no requests for additional supplies for ten days past.

Coal consumers who had accumulated stocks are now drawing upon them, but predictions are made that on the advent of bad weather this will cease, on account of the expense, and that the consumers will come into the market again.

There is no definite word as to when the Fuel Administration will relinquish its control of prices. All that is known is that the formerly expressed intention of removing control by about Dec. 15 has expired by limitation. While there is some softness in the market, the best grades of steam coal and all passable grades of gas coal are quotable at the full Government limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district. Brokers are now unable to obtain any brokerage from buyers, above the set figures, but can sometimes obtain a brokerage from the seller.

TORONTO

Anthracite coming forward freely. Dealers taking orders for small lots. Market overstocked with bituminous and prices unsettled.

Coal shipments have been coming forward freely since the close of navigation and dealers are overtaking delayed deliveries. Orders are now being taken for all grades of anthracite in ton lots. The continued mildness of the weather has considerably relieved the situation, and as there is now plenty of labor to be had, it is believed that the crisis, which recently threatened to be serious, has been safely tided over. The market is still considerably overstocked with bituminous coal, for which the demand continues light and is likely to remain so until the munition plants, now closed down, have been reorganized for other lines of industry. This has tended to unsettle prices, and sales in car lots are being made in some cases at from 25c to 50c per ton below the Government rate.

BUFFALO

Big surplus of bituminous. Anthracite increasing fast. If weather conditions last, coal will be plenty. Consumers of bituminous buying of operators direct.

Bituminous—The market is becoming more inactive every day. Operators and jobbers are trying to work together in order to move the output promptly, but they are getting small support from the consumers, who see plenty of coal ahead and will hold off for a while. The holiday season, with its small output, may hold the market awhile, but it is not likely that anything will save it long unless the winter becomes severe. At the most there has been a long period of mild weather, with only a small consumption, no matter what the rest of the winter may be.

The car situation is not good. A great number of empties are crowding into the yards here, and it is feared that certain branches of shipping will have to be shut off to enable the rest to move at all. There is complaint also of a shortage of men.

At the same time consumers as a rule are indifferent. Some of the jobbers are trying to tell them that it is a mistake to allow their supply to run down, even if there is a chance of breaking the market. A stoppage for want of coal would more than neutralize any advantage gained from a decline in the price.

Anthracite—The local situation is improving fast. Distributors report that they are getting more coal in a week than they did in all November. Retailers are working hard to keep up with the supply, and the best of it all is that the local fuel administration sees scarcely anyone asking for coal, in place of the long row of pleaders that was there a year ago. It is predicted that ten days or so of this sort of thing will make the whole situation quite easy, if it does not soon drive the fuel office out of existence.

All this flow of coal here is due to the close of the lake trade, and it is supposed that the other all-rail points in this direction from the mines have been supplied in the same liberal manner as is the case with Buffalo. Natural gas is scant, but as a rule it is sufficient where it is allowed to be used. No increase of it is promised.

CLEVELAND

Stagnation in the steam coal and domestic market is having its complement in curtailed operations in the No. 8 district, where disaffection among the miners and their protestations that the wage scale question be now opened have become much more pronounced. Not in months has the local market been so stagnant. Many operators are fast approaching the point where they feel they should shade government prices if it will bring business to help offset high costs.

Bituminous—Practically the last vestige of optimism has disappeared from the local steam-coal and domestic markets. The tonnage now moving into Cleveland and northern Ohio has shrunk almost to the zero point. Continued open weather has brought the retail trading down to a mere shadow of its normal self. With all war contracts in this district cancelled many large steam-coal users have shut down, while others have taken advantage of the lull to make repairs that war's exigencies compelled the postponement of for several years. Inventory time also has contributed its slowing up of business, and industrial prospects now appear the worst since the war's end.

As a result, No. 8 district mines are being closed daily and those that are being worked are only on half time. Restlessness among the miners over the end of the war and the question of higher wages has spread from the Pomeroy district to the No. 8. As yet no open demands have been made, but the men are making no efforts to conceal their belief that the signing of the armistice ended the war and that they are entitled to higher wages because of their efforts during the war. Operators claim that union officials are with them, and declare they will not consider wages at this time. No market and disgruntled labor combine to make eastern and southern Ohio's coal output not more than 40 per cent. of normal, if that much.

In the past week several small brokers have offered what they described as No. 8 mine-run at $2.10 or 25c. below the maximum. It is believed that this is not standard No. 8 coal. The larger operators reaffirm their inability to make any concession at the present prices and their intention of closing down entirely if necessary. Seventy-five more days will see No. 8 coal moving toward the lower lake docks, they point out, and they can afford to bide their time. Stripping coal continues to flood the market, but there is no more demand for it at a marked concession than there is for the better grades.

The Pittsburgh Vein Operators' Association of Ohio reports that car service accorded its members in the week of Dec. 7 averaged 17.84 per cent. short. Lost production accordingly was 71,350 tons. Shipments in the week of Dec. 7 totaled 5213 cars, which compares with 5264 cars the first week preceding and 4742 the second.

Anthracite—Receipts are a trifle heavier, but not yet enough to make possible anything resembling a market. Demand has fallen off to rock bottom, and efforts to produce additional shipments have been abandoned.

DETROIT

With an over-plentiful supply of bituminous in many retail yards and in stock piles of steam plants, new business in Detroit is greatly curtailed.

Bituminous—Complaints are still being made by Detroit jobbers and wholesalers that business is greatly restricted by the presence of unusually large stocks of bituminous coal in the reserve piles of the steam plants and in the yards of retail dealers. The inactive state of the market is to a considerable degree the result of unseasonably high temperatures.

Because of the weather, the market has lacked an important stimulating factor. Consumption has been of smaller volume both in the steam and domestic branches of the trade. Manufacturing plants which are numbered among the largest buyers of steam coal are in many cases holding reserves almost out of proportion to their needs, while a large number of the retailers have so much bituminous coal on hand that their yards afford no space for further stocks.

A plan to relieve the retail dealers by negotiating the sale of 25,000 tons or so of the excess stock to the City of Detroit has failed of realization. The Detroit common council, after considering the proposition made by the retailers, voted against its acceptance. This action doubtless was influenced by the fact that the city is now receiving all the coal it requires direct from the mines, and at a price from 25 to 35c. a ton cheaper than the retailers could afford to sell. The higher cost of the dealers' coal is accounted for by the 7 per cent. tax on freight charges and the extra expense involved in rehandling the coal now in their yards.

Anthracite—While little increase in receipts of anthracite is reported, the weather has made possible a substantial reduction in consumption, easing the pressure on dealers. The state fuel administration has announced modifications of earlier restrictions. Under the new rules all chestnut is reserved for baseburner users, other consumers are permitted to receive up to 50 per cent. of their fuel requirements of stove or egg sizes and all restrictions are removed from other sizes of anthracite, and from bituminous coal and coke. Considerable coke has been made available for domestic use by diversion from industrial plants that have been relieved of war contracts. Household consumers may now buy either gas or byproduct coke up to the full limit of their fuel requirements.

COLUMBUS

The coal trade in Ohio continues quiet to the extreme. There is little demand for either steam or domestic grades, and purchasers are paying a waiting game. Warm weather continues to hamper the retail business.

Because of the prevalence of balmy weather, and also because of the fact that a large percentage of householders have stored their coal, there is little retail demand. It will require a cold spell to bring consumers in the market. Retailers have rather large stocks and are thus not disposed to buy until they have moved some of their surplus. Pocahontas is now coming into the local market and practically all dealers have taken on a small supply. Retail prices are being cut for the first time since the increase in prices several years ago. This is done in order to keep teams and trucks busy. The cut is not sufficient to demoralize the market and amounts to about 50 to 65c. on the ton. Rural dealers are expecting a fair trade shortly after the holidays as farmers have been too busy to haul their fuel supply.

The steam trade is absolutely quiet. Only a few scattering orders are received, and cancellations of standing orders are frequent. Consumers are loath to buy under present unsettled conditions, and they are using up their surplus stocks. Many consumers had stored fuel to last from three to five months. Manufacturing plants in non-war work are rather slow to resume operations, but it is expected that quite a few will start up after the first of the year. War plants are gradually shutting off and their fuel requirements are being reduced accordingly. Railroads are not taking any great amount, as the freight movement is somewhat reduced. Taking it all in all, the steam trade is the most quiet in years and operators as well as shippers believe it will continue slow for some time.

Production is being curtailed to a large degree by lack of orders. Then, again, the influenza epidemic is still prevalent and that is reducing the output in all fields. Lack of orders and cancellations are cutting into the amount mined, and it is estimated at about 35 to 45 per cent. in the Hocking Valley.

CINCINNATI

Somewhat cooler weather has stimulated domestic demand, but steam market is still quiet, and production is ample for all departments.

The coldest weather of the season was experienced during the past week, but this did not mean anything much below freezing, and that only during the night. The days have remained very mild for so late in the winter, and the forced consumption of fuel, for heating purposes, remains at an astonishingly low level, everything considered. Domestic consumers in a few instances seem to have come into the market as a result of the mild cold snap, but for the most part the summer storage is taking care of the situation without difficulty.

Consumption up to this time has probably been the lightest of any winter season in years, and it seems reasonable to conclude that in all probability consumers who placed coal in storage will have very nearly enough to run them through the winter, unless January and February should bring some extremely cold weather. The quiet condition of various manufacturing lines is contributing, as for several weeks past, to a quiet market for steam fuel, and as the usual dullness of the holiday season is accentuated this year by the uncertainty and cancellation of orders resulting from the war, no improvement in the demand in this quarter can be expected soon. In short, the coal trade ate a good-sized slice of its cake in the summer, and that bids fair to be about all it will get, unless conditions both as to weather and industrial demand change very emphatically soon.

LOUISVILLE

Market on better grades of coal slightly stronger, due to lower production. River coal feared by rail operators. Wagon mines on last legs. General demand for coal light.

Many large producing mines in the eastern as well as western Kentucky fields are beginning to close down for the holiday season, being short of orders, while miners are better fixed than usual, and anxious to lay aside work and take things easy after a strenuous production season. Some of the smaller mines are being forced to quit, or work on a two- or three-day basis for lack of business. Such mines as will operate throughout the month and early January expect to produce only about 40 per cent. of the usual tonnage. This lighter production is resulting in the market being a little firmer on good grades of coal, although some producers are absorbing the brokerage, and selling at 15c. a ton under Government prices.

At the present time the retail as well as steam demand is dull. Good domestic coals have not been cut in price to any extent, as stocks are not overly large, many retailers being stocked on low grades and endeavoring to cut these down before again entering the market. Low-grade domestic is hard to sell, and practically all grades of steam need a marketing organization of merit in order to get moved.

Producers in the eastern Kentucky sections handling coal into Louisville, Cincinnati and other river towns, are now feeling that river coal movement may be a menace to business, due to the fact that freight rates for rail coal are at least 25 per cent. higher than they were, whereas the river coal companies can transport coal at probably only 10c. a ton over former costs, as the increased cost will represent labor and barges only. Now that the West Virginia mines, and some in the Pittsburgh fields, are short of business, it is feared that a considerable quantity of river coal will come south on good boating stages.

Wagon mines are having a hard fight to maintain themselves, as they have no selling organizations; the jobbers and large consumers are not going to them for coal, and the poorer quality coal is not in much demand. Some of these mines have been reported to have cut prices as much as 50c. a ton in order to get business. However, many of them are closing down, and labor is drifting to the tipple mines.

The car supply has been generally good, although the distribution has not been what it should. Whereas long lines of empties are on sidings waiting demand at mines, some mines have been forced to lay off while awaiting deliveries of empties, especially on the lines of the Southern.

Railroads in Kentucky and neighboring states have been buying coal a little more freely, there being a fair demand for coal for railroad consumption. The Southern R.R. and the Louisville & Nashville have been buying engine coal in fair lots during the past few days.

BIRMINGHAM

Active buying and scarcity of coal feature local trade conditions. Production improved to some extent but output not adequate to present needs.

There is little or no steam coal available for the spot trade. Contract consumers have been in the market the past week endeavoring to supplement the tonnage being received from regular shippers, who, for several weeks past, have been unable to supply the tonnage called for by contract buyers. On account of the shortage in supply, industries, public utilities, railroads and furnace companies are not making much headway in stocking for the holidays, but on the contrary have been forced in many instances to resort to stockpiles to meet current requirements.

No improvement is noted in the receipts of domestic coal, and the scarcity of this grade is more pronounced than in the case of steam fuel. It is a common sight to see yards which in normal times carried several thousand tons at all times, which are now perfectly bare.

Coal production for the week ending Dec. 7, showed an increase of about 60,000 net tons over the previous week, but a heavy decline in output is being anticipated around the holidays.

Coke

CONNELLSVILLE

Coke is scarce. Uncertain prospects as to continuance of price control. Holidays and bad weather promise curtailment in output.

Coke continues very scarce, furnace being hardly obtainable at all in the open market, while foundry coke is only in moderate supply and commands the Government limit except that many producers are willing to allow a brokerage to middlemen. Production of coke by byproduct ovens is approximately up to normal, the byproduct ovens being fairly well supplied with coal, and in many cases with coal of better grade than they were forced to use during the war. Connellsville coke production has increased a trifle, but is still between 50,000 and 75,000 tons a week below the rate of last September. Furnace requirements seem to be as heavy as ever, scarcely any furnaces having been blown out.

There is still nothing definite as to what the Fuel Administration will do in the matter of relinquishing control of prices. The program adopted seems to have been to close up the entire work by Dec. 31, but furnaces continue to importune the Fuel Administration to continue functioning, in view of the present scarcity of coke and the prospect that prices would advance if the control were taken off. The furnaces represent that in accordance with the general program of the steel trade prices are to be readjusted downward, and the steel producers have already accepted the reductions suggested for them; but as the blast furnaces have not reduced their pig-iron prices according to the suggestion, their claim for lower coke prices has correspondingly less standing.

Production of Connellsville coke in Christmas week is expected to show a great decrease, and winter weather, already long overdue, would effect a decrease of its own besides. It remains to be seen whether, in the event of removal of Government control and a tendency of the coke market to advance, furnaces would pay higher prices or would bank their stacks as a demonstration against the coke producers. The market remains quotable firm at the Government limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over 3-in., $7.30; clean screenings over ½-in., $5.50, per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Dec. 14 at 283,865 tons, an increase of 11,215 tons, and raw coal shipments at 213,900 tons, an increase of 19,809 tons.

Buffalo—The scarcity reported lately continues, which means that labor is hard to get and the car situation is not of the best. The local byproduct plants are running at full capacity, and with fairly good coal supply it is likely that the beehive output will come back to normal in time to keep the furnaces running on good time. All ore by lake is now in, but the final figures have not been made up. The amount is considerably more than in any former season, at this port as well as generally. Fuel coke suffers from the slackness of soft coal, but sells well where competing with anthracite.

Middle Western

MILWAUKEE

Anthracite grades, except buckwheat, advanced 90c. per ton. Soft coal unchanged in price; supply abundant, but demand slow, owing to weather conditions.

Milwaukee coal dealers have been authorized by the fuel administration to advance anthracite grades, with the exception of buckwheat, 90c. per ton. The schedule now calls for $12.77 for nut, $12.68 for stove, $12.46 for egg, $11.30 for pea and $10 for buckwheat. An extra charge of 50c. per ton is allowed when coal is carried in to bins. Coal received by rail is allowed a premium of over and above these rates.

The soft-coal market is dull, but prices have undergone no change. Hocking, Youghiogheny and Pittsburgh No. 6 sell for $7.95, delivered, and splints and West Virginia egg and lump at $8.45. Coke also commands the old price, $12 per ton. Mild weather has checked the demand for soft coal.

The foregoing price schedule will probably hold throughout the winter, unless heavy snows should increase the cost of delivery, as was the case last season.

The closing days of the season of lake navigation were characterized by a heavy run of anthracite coal, receipts during the first 14 days of December exceeding in amount those of any full month during the entire season. When it became apparent that Milwaukee was liable to go into the winter minus her full quota of hard coal, State Fuel Administrator Fitzgerald and others hurried to Washington and secured an order for prompt shipment of the needed balance. Ten large cargoes of anthracite reached port during the last week of the season. December's receipts aggregated 126,417 tons of anthracite and 29,500 tons of bituminous, making the season's cargo receipts 802,265 tons of the former and 3,432,383 tons of the latter. This shows a loss, as against last year's record, of 120,273 tons of anthracite and a gain of 286,552 tons of bituminous.

The supply of anthracite will soon be exhausted, and unless additional consignments are permitted to come by rail, many consumers will be compelled to resort to soft coal before the winter is over.

Twenty-six emergency coal stations have been opened at as many points in Milwaukee by the County Council of Defense, where fuel will be supplied to the poor in quantities of from 50 to 300 lb., on the cash-and-carry plan. The rules of the Federal Fuel Administration will be strictly adhered to. Investigation developed the fact that small dealers who peddle coal in bushel lots were getting about $20 per ton for anthracite.

General Statistics

NORFOLK & WESTERN

Following is a statement of the coal tonnage from mines on the Norfolk & Western and from other railroads, for the month of October, 1918:

From	Net Tons
Pocahontas field	1,523,691
Tug River district	307,430
Thacker district	222,125
Kenova district	61,535
Clinch Valley district	132,267
Other Norfolk and Western fields	9,552
Total Norfolk and Western fields	2,256,600
Williamson & Pond Creek R. R.	184,156
Tug River & Kentucky R. R.	54,978
All other railroads	86,836
Grand Total	2,582,570

RECORD COAL SHIPMENTS ON LAKES

A record for soft coal shipments on the Great Lakes was set during the season which has just closed. The vessels of the Lakes loaded 28,153,317 tons. This is an increase of more than one million tons over 1917. Shipments from the different ports for the season, according to reports received by the Ore and Coal Exchange, are as follows:

Port	Tons
Toledo	10,074,787
Sandusky	2,389,150
Huron	2,094,324
Lorain	3,342,681
Cleveland	3,217,801
Fairport	271,148
Ashtabula	3,405,365
Conneaut	2,212,947
Erie	1,145,114
Total	28,153,317
